NUMERICAL VS CONVENTIONAL ANALYSIS

method of analysis	Equil.	Comp.	Const. Behav.	B.C. Force	B.C. Displ.
Closed form	yes	yes	linear elastic	yes	yes
Limit equilibrium	yes	no	rigid with failure criterion	yes	no
Lower bound	yes	no	ideal plasticity with associated flow	yes	no
Upper bound	no	yes	ideal plasticity with associated flow	no	yes
Beam-spring	yes	yes	springs	yes	yes
Numerical analysis	yes	yes	any	yes	yes

THE FINITE ELEMENT METHOD

- is a versatile numerical method to obtain **(approximate)** solutions to **mathematical problems** (the governing mathematical equations are approximated by a series of **algebraic** equations involving quantities that are evaluated at discrete points within the region of interest)

$$\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{xy}}{\partial y} + \frac{\partial \tau_{xz}}{\partial z} = b_x \quad \longrightarrow \quad a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = c_1$$

- has been extensively used in many areas of engineering (and other disciplines)
- has a long tradition in geotechnical research
- has been developed to a stage where user-friendly codes at a high technical level are commercially available, some of them designed specifically for geotechnics

FEM has become a standard (design) tool in practical geotechnical engineering

THE FINITE ELEMENT METHOD

What kind of problems?

Though we would like to know our solution at any coordinates in our project, we will only calculate them in a certain amount of discrete points (nodes) and estimate our solution anywhere else

> **discretization:** This is the process of modelling the geometry of the problem under investigation by an assemblage of small regions, termed finite elements. These elements have nodes defined on the element boundaries, or within the elements.

Primary variable approximation: A primary variable must be selected (e.g. displacements) and rules as how it should vary over a finite element established. This variation is expressed in terms of nodal values.

- A **polynomial form** is assumed, where the order of the polynomial depends on the number of nodes in the element.
- The higher the **number of nodes** (the order of the polynomial), the more accurate are the results.

BASICS STEPS OF FINITE ELEMENT ANALYSIS

Define geotechnical problem and purpose of analysis

Define model for analysis
boundary conditions, domain to be analysed,...

Mesh generation, choose type of elements
continuum, beams, membran, ...

BASICS STEPS OF FINITE ELEMENT ANALYSIS

define and assign material parameters

define loading / construction stages

solve equation system > displacements as primary variables
(not necessarily required but most popular formulation)

strains > stresses

critical assessment of results
of paramount importance in geotechnics

BASICS OF FINITE ELEMENT METHOD

Typical 2D mesh for deep excavation

Hints for modelling:

- finer where high gradients are expected
- aspect ratio (careful with highly distorted elements)

BASICS OF FINITE ELEMENT METHOD

- isoparametric elements
- polynomial interpolation of displacements within element
- higher order > more accuracy

(b) Lagrange elements

BASICS OF FINITE ELEMENT METHOD - RESULTS

- **Primary unknowns (displacements in stress analysis) at *nodes***
- **Stresses and strains are most accurate in *integration points***
- **Internal forces (e.g. bending moments) in structural elements (e.g. beams and plates)**
- **Information which stress points have reached ultimate strength**

most codes provide comprehensive graphical output of contourlines for displacement and stress components, (excess) pore pressures, strength mobilisation etc.

BASICS OF FINITE ELEMENT METHOD

BASICS OF FINITE ELEMENT METHOD

BASICS OF FINITE ELEMENT METHOD

Total displacements u_x

Maximum value = $1,893 \cdot 10^{-3} \text{ m}$ (Element 20 at Node 2838)

Minimum value = $-0,02540 \text{ m}$ (Element 2961 at Node 4030)

BASICS OF FINITE ELEMENT METHOD

Maximum value = 1,000 (Element 1845 at Node 3492)

Minimum value = 0,01677 (Element 420 at Node 10786)

BASICS OF FINITE ELEMENT METHOD

Total displacements u_x

Maximum value = 3.016×10^{-3} m (Element 69229 at Node 190928)

Minimum value = -0.01685 m (Element 15314 at Node 181960)

BASICS OF FINITE ELEMENT METHOD

Total displacements u_x

Maximum value = 0,03251 m (Element 69148 at Node 216879)

Minimum value = $-9,067 \cdot 10^{-3} \text{ m}$ (Element 116485 at Node 85409)

BASICS OF FINITE ELEMENT METHOD

CONCLUDING REMARKS

Objectives of the numerical (finite element) analysis

- Selection of design alternatives
- Quantitative predictions
- Backcalculations
- **Understanding!**
 - Identification of critical mechanisms
 - Identification of key parameters

CONCLUDING REMARKS

Advantages of numerical (finite element) analysis

- Simulation of complete construction history
- Interaction with water can be considered rigorously
- Complex geometries (2D-3D) can be modelled
- Structural elements can be introduced
- No failure mechanism needs to be postulated (it is an outcome of the analysis)

(Nearly) unavoidable uncertainties

- Ground profile
- Initial conditions (initial stresses, pore water pressure...)
- Boundary conditions (mechanical, hydraulic)
- Appropriate model for soil behaviour
- Model parameters

CONCLUDING REMARKS

Some requirements for successful numerical modelling

- Construction of an adequate conceptual model that includes the basic features of the model. *The model should be as simple as possible but not simpler.*
- Selection of an appropriate constitutive model. It depends on:
 - type of soil or rock
 - goal of the analysis
 - quality and quantity of available information
- Pay attention to patterns of behaviour and mechanisms rather than just to quantitative predictions.
- Perform sensitivity analyses. Check robustness of solution.
- Model calibration (using field results) should be a priority, especially when quantitative predictions are sought.
- Check against alternative computations if available (even if simplified).

FINAL REMARKS

- 1. Geotechnical engineering is complex. It is not because you are using the FEM that it becomes simpler.**
- 2. The quality of a tool is important, yet the quality of a result also (mainly) depends on the user's understanding of both the problem and the tool.**
- 3. The design process involves considerably more than analysis.**

LINEAR ELASTIC - PERFECTLY PLASTIC

One-dimensional

IMPORTANT: yield stress = failure stress for perfect plasticity

$$\varepsilon = \varepsilon^e + \varepsilon^p$$

General three-dimensional stress state

$$\begin{Bmatrix} \varepsilon \end{Bmatrix} = \begin{Bmatrix} \varepsilon \end{Bmatrix}^e + \begin{Bmatrix} \varepsilon \end{Bmatrix}^p$$

LINEAR ELASTIC - PLASTIC

One-dimensional

IMPORTANT: yield stress $\neq$ failure stress

$$\epsilon = \epsilon^e + \epsilon^p$$

General three-dimensional stress state

$$\begin{Bmatrix} \epsilon \end{Bmatrix} = \begin{Bmatrix} \epsilon \end{Bmatrix}^e + \begin{Bmatrix} \epsilon \end{Bmatrix}^p$$

LINEAR ELASTIC - PLASTIC WITH SOFTENING

One-dimensional

Note: modelling strain softening behaviour needs enhancement of finite element formulation > at present not possible with Plaxis

Y_0 = yield stress

Y_F = failure stress

THEORY OF PLASTICITY

For describing linear elastic - plastic material behaviour we need
(for general stress states):

1. Stress-strain behaviour in elastic range
2. **Yield function or failure function**
(defines onset of plastic deformation)
3. **Flow rule**
(defines direction of plastic strain increment)
4. **Definition of strain hardening (softening)**
(defines change of yield function with stress and/or strain)

For standard MC-model:

- Linear elasticity in elastic range
- No strain hardening/softening > perfect plasticity

MOHR COULOMB CRITERION

Mohr-Coulomb yield function

yield function:
$$f = \frac{1}{2}(\sigma_1' - \sigma_3') - \frac{1}{2}(\sigma_1' + \sigma_3') \sin \varphi' - c' \cos \varphi$$

σ_1' and σ_3' : major and minor principal stresses

sign convention

positive: tensile stress, elongation, volume increase

negative: compressive stress, compression, volume decrease

MOHR COULOMB MODEL - PLASTIC POTENTIAL

$$f = \frac{1}{2}(\sigma'_1 - \sigma'_3) - \frac{1}{2}(\sigma'_1 + \sigma'_3) \sin \phi' - c' \cos \phi$$

dilatancy angle

$$\dot{g} = \frac{1}{2}(\sigma'_1 - \sigma'_3) + \frac{1}{2}(\sigma'_1 + \sigma'_3) \sin \psi' + \text{const.}$$

DILATANCY

Model

loose soils are
non-dilatant or
contractant

$$\psi = 0$$

dense soils are
dilatant

$$\psi \neq 0, \text{ but } < \phi'$$

Mechanism

loose

dense

strength = friction + dilatancy

DILATANCY

Simple shear test (drained)

$$G = \frac{E}{2(1 + \nu)}$$

$$\tan \psi = \frac{\Delta \epsilon_{xy}}{\Delta \epsilon_{yy}}$$

DILATANCY

Triaxial test (drained)

$$E = \frac{\Delta |\sigma_y - \sigma_x|}{\Delta |\varepsilon_y|} = 2G(1 + \nu)$$

$$\varepsilon_v = 2\varepsilon_x + \varepsilon_y$$

$$\tan \alpha = \frac{2 \sin \psi}{1 - \sin \psi}$$

MOHR COULOMB MODEL - PARAMETERS

E	Young's modulus	[kN/m ²]
ν	Poisson's ratio	[-]
c'	(effective) cohesion	[kN/m ²]
φ'	(effective) friction angle	[°]
ψ	dilatancy angle	[°]

MOHR COULOMB MODEL - SUMMARY

- **Simple elastic perfectly-plastic model**
- **Suitable for some practical applications**
(not for deep excavations and tunnels)
- **Limited number and clear parameters**
- **Good representation of failure behaviour (drained)**
- **Dilatancy can be considered**

MOHR COULOMB MODEL - SUMMARY

- **Isotropic behaviour**
- **Linear elastic** behaviour until failure
- **No stress-dependent stiffness**
- **No distinction between primary loading and unloading / reloading**
- **Constant dilatancy (non-associated flow)**
(for associated flow dilatancy would be significantly overpredicted)
- **Undrained behaviour not realistic (in particular for soft soils)**
- **No anisotropy, no time-dependency (creep)**

STRAIN HARDENING

One-dimensional

$$f(\{\sigma\}, \{\epsilon\}^p) = 0 \quad \text{more general} \quad f(\{\sigma\}, h) = 0 \quad \text{with} \quad h = f(\{\epsilon\}^p)$$

STRAIN HARDENING (FOR ADVANCED MODELS)

Two-dimensional

Schematic representation of isotropic hardening (all models in Plaxis at present)

STRAIN HARDENING (FOR ADVANCED MODELS)

Two-dimensional

Schematic representation of kinematic hardening

CG03 Exercise 1-Modelling of a Strip Foundation

William W.L CHEANG PhD MSc PGDip BEng (Hons)

Contents

1. Introduction
2. Plaxis Finite Element Model
3. Modelling Stages
4. Results
5. Discussion
6. Additional work

This is CG3 (Exercise 1)

1. This exercise is related to **CG 1** (Concepts of Plasticity and Mohr Coulomb Model)
2. We will use an **Elasto Perfectly Plastic Model** with **Mohr-Coulomb** failure criterion.
3. We will model a **simple strip foundation** (reason being, we are familiar with the calculation of Ultimate Bearing Capacity). This boundary value problem is related to ground loading and we are basically doing an FEM validating exercise.
4. We will look at the **Long Term (Drained)** condition in this first part of the exercise (1A).
5. Additional exercise (1B), we will simulate **Short Term condition (Undrained)**.

The problem

One of the simplest forms of a foundation is the shallow foundation. In this exercise we will model such a shallow foundation with a width of 2 meters and a length that is sufficiently long in order to assume the model to be a plane strain model. The foundation is put on top of a 4m thick clay layer. The clay layer has a saturated weight of 18 kN/m^3 and an angle of internal friction of 20° .

Figure 1: Geometry of the shallow foundation.

The problem (continuation..)

The foundation carries a small building that is being modelled with a vertical point force. Additionally a horizontal point force is introduced in order to simulate any horizontal loads acting on the building, for instance wind loads. Taking into account that in future additional floors may be added to the building the maximum vertical load (failure load) is assessed. For the determination of the failure load of a strip footing analytical solutions are available from for instance Vesic, Brinch Hansen and Meyerhof:

$$\begin{aligned} \frac{Q_f}{B} &= c \cdot N_c + \frac{1}{2} \gamma' B \cdot N_\gamma \\ N_q &= e^{\pi \tan \varphi'} \tan^2(45 + \frac{1}{2} \varphi') \\ N_c &= (N_q - 1) \cot \varphi' \\ N_\gamma &= \begin{cases} 2(N_q + 1) \tan \varphi' & (\text{Vesic}) \\ 1.5(N_q - 1) \tan \varphi' & (\text{Brinch Hansen}) \\ (N_q - 1) \tan(1.4 \varphi') & (\text{Meyerhof}) \end{cases} \end{aligned}$$

This leads to a failure load of 117 kN/m² (Vesic), 98 kN/m² (Brinch Hansen) or 97 kN/m² (Meyerhof) respectively.

The problem (in the Appendix)

Bearing capacity calculation based on

Vesic, Meyerhof & Brinch Hansen

1. These are the values we used to compare with our FEM model
2. Important to see the close agreement (Build confidence & understanding)
3. Also, you can use (re-use) this model to check FEM code (s) and future release/updates in PLAXIS.

APPENDIX A: BEARING CAPACITY CALCULATION

Given the formula for bearing capacity of a strip footing:

$$\begin{aligned} \frac{Q_f}{B} &= c \cdot N_c + \frac{1}{2} \gamma' B \cdot N_\gamma \\ N_q &= e^{\pi \tan \varphi'} \tan^2(45 + \frac{1}{2} \varphi') \\ N_c &= (N_q - 1) \cot \varphi' \\ N_\gamma &= \begin{cases} 2(N_q + 1) \tan \varphi' & (\text{Vesic}) \\ 1.5(N_q - 1) \tan \varphi' & (\text{Brinch Hansen}) \\ (N_q - 1) \tan(1.4 \varphi') & (\text{Meyerhof}) \end{cases} \end{aligned}$$

Filling in given soil data:

$$\begin{aligned} N_q &= e^{\pi \tan(20)} \tan^2(55) = 6.4 \\ N_c &= (6.4 - 1) \cot(20) = 14.84 \\ N_\gamma &= \begin{cases} 2(6.4 + 1) \tan(20) = 5.39 & (\text{Vesic}) \\ 1.5(6.4 - 1) \tan(20) = 2.95 & (\text{Brinch Hansen}) \\ (6.4 - 1) \tan(28) = 2.97 & (\text{Meyerhof}) \end{cases} \end{aligned}$$

The effective weight of the soil:

$$\gamma' = \gamma_w - 10 \text{ kN/m}^3 = 18 - 10 = 8 \text{ kN/m}^3$$

For a strip foundation this gives:

$$\frac{Q_f}{B} = c \cdot N_c + \frac{1}{2} \gamma' B \cdot N_\gamma = \begin{cases} 5 \cdot 14.84 + \frac{1}{2} \cdot 8 \cdot 2 \cdot 5.39 = 117 \text{ kN/m}^2 & (\text{Vesic}) \\ 5 \cdot 14.84 + \frac{1}{2} \cdot 8 \cdot 2 \cdot 2.95 = 98 \text{ kN/m}^2 & (\text{Brinch Hansen}) \\ 5 \cdot 14.84 + \frac{1}{2} \cdot 8 \cdot 2 \cdot 2.97 = 97 \text{ kN/m}^2 & (\text{Meyerhof}) \end{cases}$$

PLAXIS FEM MODEL AND SIMULATION

1. First, we model the problem in “Drained” condition (Long-term).

- a) We look at the movement of the strip foundation
- b) We'll look at the failure mechanism
- c) We will plot calculate/find the ultimate bearing capacity

2. Additional exercise.

- a) In continuation with “Drained” model we will proceed with simulating the problem for short-term condition
- b) In Plaxis we use the “Undrained” drainage type.
- c) Can you calculate the Short-term bearing capacity value?

The complete Model

STEPS IN PLAXIS AE

MODES: SOIL > STRUCTURES > MESH > WATER > STAGE

- Input

- Start new project
- Soil mode
 - * Create soil layers
 - * Create and assign soil material sets
- Structures mode
 - * Create footing
 - * Create load
- Mesh mode
 - * Generate mesh
- Staged construction mode
 - * Determine initial situation
 - * Calculation of vertical load representing the building weight
 - * Calculation of vertical and horizontal load representing building weight and wind force
 - * Calculation of vertical failure load.

The geometry and loading conditions

Figure 1: Geometry of the shallow foundation.

The geometry and loading conditions

The geometry and loading conditions

Plaxis Model: Graphical User Interface

Some information on calculation stages

RESULTS

DRAINED MODEL

Output 1: Deformed mesh at “True

Deformed mesh |u| (at true scale)
Maximum value = 0.1162 m (Element 7 at Node 782)

Output 2: Vectors

Output 4: Incremental Displacements

Output 4: Incremental shear strains

Incremental deviatoric strain $\Delta\gamma_s$

Maximum value = $2.045 \cdot 10^{-3}$ (Element 208 at Node 931)

Minimum value = $0.6678 \cdot 10^{-9}$ (Element 7 at Node 782)

Solution of Vesic, Brinch-Hansen & Meyerhof

Given the formula for bearing capacity of a strip footing:

$$\begin{aligned} \frac{Q_u}{B} &= c \cdot N_c + \frac{1}{2} \gamma' B \cdot N_q \\ N_q &= e^{K \tan \phi} \tan^2(45^\circ + \frac{1}{2} \phi') \\ N_c &= (N_q + 1) \cot \phi' \\ N_q &= \begin{cases} 2(N_q + 1) \tan \phi' & \text{(Vesic)} \\ 1.5(N_q + 1) \tan \phi' & \text{(Brinch Hansen)} \\ (N_q + 1) \tan(1.4 \phi') & \text{(Meyerhof)} \end{cases} \end{aligned}$$

Filling in given soil data:

$$\begin{aligned} N_q &= e^{K \tan \phi} \tan^2(45^\circ + \frac{1}{2} \phi') = 6.4 \\ N_c &= (6.4 + 1) \cot(20^\circ) = 14.84 \\ N_q &= \begin{cases} 2(6.4 + 1) \tan(20^\circ) = 5.39 & \text{(Vesic)} \\ 1.5(6.4 + 1) \tan(20^\circ) = 2.95 & \text{(Brinch Hansen)} \\ (6.4 + 1) \tan(28^\circ) = 2.97 & \text{(Meyerhof)} \end{cases} \end{aligned}$$

The effective weight of the soil:

$$\gamma' = \gamma_{sat} - 10 \text{ kN/m}^3 = 18 - 10 = 8.1 \text{ kN/m}^3$$

For a strip foundation this gives:

$$\frac{Q_u}{B} = c \cdot N_c + \frac{1}{2} \gamma' B \cdot N_q = \begin{cases} 5 + 14.83 + \frac{1}{2} \cdot 8 \cdot 2 = 117 \text{ kN/m}^2 & \text{(Vesic)} \\ 5 + 14.83 + \frac{1}{2} \cdot 8 \cdot 2.95 = 98 \text{ kN/m}^2 & \text{(Brinch Hansen)} \\ 5 + 14.83 + \frac{1}{2} \cdot 8 \cdot 2.97 = 97 \text{ kN/m}^2 & \text{(Meyerhof)} \end{cases}$$

Output 5: Load-settlement curve

Ultimate Bearing Pressure

$$Q_u / B = (\text{Maximumn Load} / B) + (\gamma_{conc} * d)$$

$$Q_u / B = (221 / 2) + (24 * 0.25)$$

Extra: FEM, Descretisation & Element Type

Table 2: Results for the maximum load reached on a strip footing on the drained sub-soil for different 2D meshes

Exercise 1A (3D Model)

Model: Exercise 1B – Undrained Model

When saturated soils are loaded rapidly, the soil body will behave in an undrained manner, i.e. excess pore pressures are being generated. In this exercise the special PLAXIS feature for the treatment of undrained soils is demonstrated.

HARDENING SOIL SMALL MODEL

Helmut F. Schweiger¹⁾ dan Indra Noer Hamdhan ²⁾

¹⁾ Computational Geotechnics Group
Institute for Soil Mechanics and Foundation Engineering
Graz University of Technology

²⁾ Civil Engineering Department
National Institute of Technology (Itenas) Bandung

CONTENTS

- Introduction (why advanced model?)
- Short description of Hardening Soil Model
- Parameters of Hardening Soil Model
- Comparison with experimental data
- Influence of important parameters
- Extension to account for small strain stiffness (HS-Small)
- Summary

Soil behaviour includes:

- difference in behaviour for primary loading – reloading/unloading
- nonlinear behaviour well below failure conditions
- stress dependent stiffness
- plastic deformation for isotropic or K_0 -stress paths
- dilatancy is not constant
- small strain stiffness (at very low strains and upon stress reversal)
- influence of density on strength and stiffness

**cannot be accounted for with simple
elastic-perfectly plastic constitutive models**

Real test

Mohr-Coulomb model

HS

MC

TRIAXIAL TEST

Applied stress path and results for standard drained triaxial test

q_f = failure value

q_r = residual value

$$\epsilon_{vol} = \epsilon_{volumetric} = \epsilon_1 + \epsilon_2 + \epsilon_3$$

HYPERBOLIC APPROXIMATION OF STANDARD DRAINED TEST

$$E_{50} = E_{50}^{\text{ref}} \cdot \left(\frac{\sigma'_3 + a}{p_{\text{ref}} + a} \right)^m$$

$$\epsilon_1 = \frac{q_a}{2 \cdot E_{50}} \cdot \frac{q}{q_a - q}$$

E_{50}^{ref} = reference modulus for primary loading at 50% of strength

$m_{\text{sand}} \approx 0.5$; $m_{\text{clay}} \approx 1$

DEFINITION OF E_{50}

STIFFNESS IN UNLOADING-RELOADING

Triaxial tests:
Unloading is purely elastic in HS model

DEFINITION OF E_{oed}

$$E_{oed} = E_{oed}^{ref} \cdot \left(\frac{c \cdot \cot \varphi + \sigma'_1}{c \cdot \cot \varphi + p_{ref}} \right)^m$$

holds strictly for K_0 -stress paths only

OVERCONSOLIDATION

Calculation of σ_{p0} based on OCR:

$$\sigma_{p0} = OCR \sigma'_{yy0}$$

Calculation of σ_{p0} based on POP:

$$\sigma_{p0} = \sigma'_{yy0} - POP$$

PLASTICITY IN HS MODEL

(unloading reloading)
2. **Plasticity**
(compression)
3. **Plasticity**
(shear)
4. **Plasticity**
(compression + shear)
5. **Plasticity**
(failure criterion)

PARAMETERS OF HARDENING SOIL MODEL

φ' friction angle
 c' cohesion
 ψ' dilatancy angle

E_{50}^{ref} **secant modulus from triaxial test** (controls deviatoric hardening)

E_{oed}^{ref} **tangential modulus from oedometer test**
 (controls volumetric hardening)

E_{ur}^{ref} **unloading / reloading modulus**

default: $E_{ur}^{ref} = 3 E_{50}^{ref}$

m **power for stress dependency of stiffness**

PARAMETERS OF HARDENING SOIL MODEL

ν_{ur} **Poisson ratio for unloading / reloading** (default $\nu_{ur} = 0.2$)

p^{ref} **reference stress**
(default $p^{ref} = 100$ stress units)

K_0^{nc} **K_0 -value for normal consolidation** (default $= 1 - \sin \varphi$)
(controls volumetric hardening)

$R_f = q_f / q_a$ (default $R_f = 0.9$)

PARAMETERS OF HARDENING SOIL MODEL

$$E_{oed}^{ref} \approx I_D \bullet 60 \text{ MPa}$$

Correlation for $p^{ref}=100 \text{ kPa}$ (Lengkeek)
 I_D = relative density

Stiffness of sand

Note: always plot E_{oed} , E_{ur} distribution for initial stress state when using HS-model

Loose sands: $E_{50}^{ref} \approx 15$ MPa

Dense sands: $E_{50}^{ref} \approx 50$ MPa

**m for clays:
approx. 0.9 – 1.0**

For normally consolidated clays (m=1):

$$E_{oed}^{ref} \approx \frac{1}{2} E_{50}^{ref}$$

Order of magnitude (very rough)

$$E_{oed}^{ref} \approx \frac{50000 \text{ kPa}}{I_p}$$

Correlation with I_p for $p^{ref}=100$ kPa

$$E_{oed}^{ref} \approx \frac{500 \text{ kPa}}{w_L - 0.1}$$

Correlation by Vermeer

$$E_{oed}^{ref} \approx p^{ref} / \lambda^*$$

Relation with Soft Soil model

Ohde / Janbu:

$$E_{oed} = E_{oed}^{ref} \left(\frac{\sigma_1'}{p_{ref}} \right)^m$$

Parameter limitations

HS model has internal parameters that are computed from our "engineering" input parameters > not all combinations of input parameters can be used. For very soft soils this could be a problem in certain cases.

e.g. $E_{50} / E_{oed} > 2$ difficult to input

INFLUENCE E_{50} / E_{oed}

SMALL STRAIN STIFFNESS

Typical curve of degradation of stiffness with strain

If the small strain stiffness model after Hardin & Drnevich predicts a stiffness lower than G_{ur}^{ref} (E_{ur}^{ref} respectively) the model switches to hardening plasticity of the standard Hardening Soil model.

IMPORTANT NOTE: flow rule for deviatoric yield surface (volumetric behaviour) is different in HSS model.

CALIBRATION OF HS MODEL

PLAXIS ADVANCED COURSE, BANDUNG, INDONESIA

INTRODUCTION

In daily engineering practice soil parameters are obtained from one or more laboratory tests. In order to perform the best possible Plaxis calculation these soil parameters have to be translated into input parameters for the constitutive model used, taking into account the possibilities and limitations of the constitutive model. Most parameters for the constitutive models used in Plaxis can be determined directly from standard laboratory tests as triaxial tests and oedometer tests. However, due to the complexity of the models it is recommended to not simply accept the parameters determined from those tests, but to actually model the tests and see if the parameters found actually give a proper representation of the real laboratory test results within the limits of the constitutive models.

In the past simulation of laboratory tests with Plaxis could only be done by creating a complete finite element model taking into account the appropriate loads and boundary conditions. Since Plaxis V8, however, a special tool is included in the software to simply simulate laboratory tests without the need for making a finite element model: the SoilTest tool.

In this exercise the SoilTest tool will be used for the simulation of both oedometer and triaxial tests on sand.

Appendix C: Comparison of the calculated and original test results

SIMULATION OF LABORATORY TESTS

In this exercise results from oedometer and triaxial tests are presented. The aim is to determine the parameters for the Hardening Soil model such that a simulation of the tests within Plaxis gives the best possible results compared to the original laboratory tests. In short:

1. Determine soil parameters based on the given soil laboratory tests results
2. Perform the laboratory tests using SoilTest with the parameters found
3. Match SoilTest results with the original laboratory results to find the best matching model parameters for the Hardening Soil model.

Exercise 1: LABORATORY TESTS ON SAND

Parameter determination

On a sample of dense sand both oedometer tests and triaxial tests have been performed. The results of those tests are given in the figures below. Use these figures to determine the parameters for the Hardening Soil model and collect the parameters in Table 1. Note that it is possible that some parameters cannot be determined with the given laboratory results, these parameters have to be estimated.

Figure 1: Oedometer test results

Figure 2: Development of horizontal and vertical stress in oedometer test

Figure 3: Drained triaxial test unloading-reloading (cell pressure = 100 kPa)

Figure 4: Axial vs. volume strain in drained triaxial test

Collect the soil parameters in table 1:

Parameter	Unit	Value
E_{50}^{ref}	[kPa]	
E_{oed}^{ref}	[kPa]

K_0^{NC}	[-]	

Table 1: Hardening Soil Parameters of the Sand

With these data perform a triaxial test in the SoilTest program.

APPENDIX B: INTRODUCTION TO THE SOILTEST TOOL

For the simulation of laboratory tests Plaxis offers the SoilTest tool based on a single stress point calculation that makes it possible to do fast simulations without the need for a finite element mesh. The SoilTest tool can be called from within the material sets database or from within the definition of a material set. (see Figure 9).

In the following paragraphs a step-by-step description is given on how to model both an oedometer test and a triaxial test with the help of many screen shots of the SoilTest tool.

Figure 5: The SoilTest tool

How to Model an oedometer test

In order to model an oedometer test first the material data set has to be created. After doing so, press the <SoilTest> button to start the SoilTest tool. The window that opens is shown in Figure 10.

Figure 6: SoilTest tool

In the main window select the *Oedometer* tabsheet and set the parameters as indicated in Figure 11.

Figure 7: Setting the oedometer parameters

After the oedometer test has been calculated, graphs with results appear at the bottom of the SoilTest window. The user can double-click these graphs to view them in separate windows. Furthermore, custom charts can be added, see Figure 12.

Figure 8: Inspecting the oedometer test results

Figure 9: Separate window

Figure 10: Data output

How to Model a triaxial test

From the material database or the material set definition window press the <SoilTest> button to start the SoilTest tool. In the main window choose the tabsheet *Triaxial* and set the type of test as well as the test parameters as shown in Figure 13.

Figure 11: Defining a triaxial test

After the triaxial test has been calculated, graphs with results appear at the bottom of the SoilTest window. As described above for the oedometer test, the user can double-click this graphs to view them in separate windows as well as add custom charts.

Modelling a triaxial test with unloading/reloading

The standard functionality in SoilTest for simulation of a triaxial test does not allow intermediate unloading-reloading paths. However, the SoilTest functionality contains a *General* option with which soil test can be defined in terms of boundary stresses or strains on all sides of a soil test cube. Hereafter it will be shown how this can be used for the simulation of a triaxial test with an unloading/reloading path.

After opening the SoilTest option from the material set definition window, the tabsheet General should be chosen. On this tabsheet a list of calculation phases can be defined where stress or strain increments can be applied.

Initial phase

First of all we have to specify whether stresses or strains will be applied on the boundaries during the test. For this exercise stresses will be applied. Now the values of the initial stresses on the soil sample have to be specified. For a triaxial test the initial stresses are the cell pressures acting on the soil, hence for σ_{xx} , σ_{yy} and σ_{zz} the cell pressure has to be entered. The cell pressure is a water pressure, there will be no shear stress acting on the soil: $\tau_{xy} = 0$. See Figure 14 for details.

Figure 12: General option for simulation of laboratory tests used for triaxial test

Phase 1

Apply a stress increment in vertical direction (σ_{yy}) until the stress level where the unloading path should start. Note that the horizontal stresses (σ_{xx} and σ_{zz}) remain the same as they represent the cell pressure. Hence, the horizontal stress increments are zero in this phase.

Phase 2

Press the <Add> button to add another phase to the phase list. This phase represents the unloading phase. See Figure 17 for details.

Phase 3

Press the <Add> button once more in order to add the 3rd phase. This phase represents the reloading of the soil as well as the continuation of primary loading until either failure or a higher stress level from where, for instance, another unloading/reloading cycle can be defined.

Figure 13: Unloading/reloading cycle in a triaxial test using the General option

APPENDIX C: COMPARISON OF THE CALCULATED AND ORIGINAL TEST RESULTS

The blue data is the original soil laboratory data and the red one is the calculated behaviour of the HS-Material based on the laboratory data. As indicated in the following figures, the numerical results with the obtained HS parameters give a proper representation of the soil tests.

Figure 14: Oedometer test results

Figure 15: Development of horizontal and vertical stress in oedometer test

Figure 16: Drained triaxial test unloading-reloading (cell pressure = 100 kPa)

Figure 17: Axial vs. volume strain in drained triaxial test (Standard Triaxialtest - cell pressure=100[kPa])

APPENDIX A: PARAMETER DETERMINATION

Sand

First we determine parameters from the triaxial test data.

Figure 1: Determine stiffness parameters from drained triaxial test

Cohesion and friction angle

For a cell pressure $\sigma_3 = 100$ kPa a maximum value of approximately $|\sigma_1 - \sigma_3| = 400$ kPa is reached at failure. The Mohr-Coulomb failure criterion is:

$$\frac{1}{2} * (\sigma_1 - \sigma_3) - \frac{1}{2} * (\sigma_1 + \sigma_3) * \sin \varphi - c * \cos \varphi = 0$$

Considering it is sand we assume that the cohesion is zero and so the Mohr-Coulomb failure criterion reduces to:

$$\frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3} = \sin \varphi$$

Filling in $\sigma_3 = 100$ kPa and $\sigma_1 = 500$ kPa as obtained from the test we find for the friction angle $\phi = 42^\circ$

Reference stiffness from triaxial test

The triaxial test stiffness E_{50} is the secant stiffness over the first 50% of the failure value for $|\sigma_1 - \sigma_3|$. This is indicated in red in the triaxial test graph of Figure 5.

$$E_{50}^{\sigma_3=100kPa} = \frac{400}{0,013} = 30800 \text{ kPa}$$

The triaxial test stiffness E_{50} is within the Hardening Soil model defined as:

$$E_{50} = E_{50}^{ref} * \left(\frac{c * \cos \varphi - \sigma_3 * \sin \varphi}{c * \cos \varphi + p_{ref} * \sin \varphi} \right)^m, c = 0 \rightarrow E_{50} = E_{50}^{ref} * \left(-\frac{\sigma_3}{p_{ref}} \right)^m$$

The reference stress p_{ref} is chosen equal to the cell pressure of this triaxial test (100kPa).

$$E_{50}^{ref} = E_{50}^{\sigma_3=100kPa} \approx 31000 \text{ kPa}$$

Reference unloading-reloading stiffness

Similar to the determination of the E_{50}^{ref} value the reference unloading-reloading stiffness can be determined. Therefore an unloading-reloading cycle is performed.

The Hardening Soil model does not have unloading-reloading behaviour with hysteresis but simple non-linear elastic unloading-reloading behaviour. A secant value is taken for the unloading-reloading behaviour, as indicated with the green line in the triaxial test results.

$$E_{ur}^{\sigma_3=100kPa} = \frac{400}{0.026 - 0.021} = 80000 \text{ kPa}$$

Under the same assumptions as for the stiffness in triaxial testing counts:

$$E_{ur}^{ref} = E_{ur}^{\sigma_3=100kPa}$$

But this is a low value for the unloading reloading stiffness and so

$$E_{ur}^{ref} = 90000 \text{ is chosen}$$

Dilatancy angle

From the plot of axial strain versus volume strain the dilatancy angle can be determined according to

$$\sin \psi = \frac{\Delta \varepsilon_v}{-2\Delta \varepsilon_1 + \Delta \varepsilon_v}$$

See Figure 6 for details.

With $\Delta \varepsilon_v = 0.048 - 0.004 = 0.044$ and $\Delta \varepsilon_1 = -0.09 - (-0.03) = -0.06$ the dilatancy can be calculated as $\psi = 16^\circ$.

Note: The Poisson's ratio needed for the Hardening Soil model **cannot** be determined from the given graphs since the Poisson's ratio needed is an unloading-reloading Poisson's ratio.

Figure 2: Determination of dilatancy angle from drained triaxial test

Oedometer stiffness and power of stress dependent stiffness

From the oedometer test results we determine the stiffness E_{oed} for vertical stresses $\sigma_{yy} = 100$ kPa and $\sigma_{yy} = 200$ kPa, see Figure 7. Note that E_{oed} is a tangent stiffness.

Make sure to use the primary loading part of the oedometer test results.

$$E_{oed}^{\sigma_y=100kPa} = \frac{320 - 0}{1.35\% - 0.33\%} = 31400 \text{ kPa}$$

$$E_{oed}^{\sigma_y=200kPa} = \frac{400 - 0}{1.35\% - 0.47\%} = 45450 \text{ kPa}$$

Within the Hardening Soil model the stress dependent oedometer stiffness is defined as:

$$E_{oed} = E_{oed}^{ref} \left(\frac{c \cos \varphi - \sigma_{yy} \sin \varphi}{c \cos \varphi + p_{ref} \sin \varphi} \right)^m, c = 0 \Rightarrow E_{oed} = E_{oed}^{ref} \left(-\frac{\sigma_{yy}}{p_{ref}} \right)^m$$

Choosing the reference pressure $p_{ref} = 100$ kPa gives

$$E_{oed}^{ref} = E_{oed}^{\sigma_y=100kPa} \approx 31000 \text{ kPa}$$

The power m for stress dependent stiffness can now be determined as:

$$\frac{E_{oed}^{\sigma_y=200kPa}}{E_{oed}^{ref}} = \left(\frac{\sigma_{yy}}{p_{ref}} \right)^m \Rightarrow \frac{45500}{31000} = \left(\frac{200}{100} \right)^m \Rightarrow m \approx 0.6$$

Figure 3: Determination of oedometer stiffness and power of stress dependency

K₀ value for normal consolidation

The K₀-value for normal consolidation can only be obtained if measurements of horizontal stresses have been performed during the oedometer test. If so, results as given in Figure 8 may be obtained. From the primary loading line it is possible to work out K₀.

$$K_0^{nc} = \frac{\Delta \sigma_x}{\Delta \sigma_y} = \frac{\Delta \sigma_3}{\Delta \sigma_1} = \frac{100}{300} = 0.33$$

Alternatively one can use Jaki's formula

$$K_0^{nc} \approx 1 - \sin \varphi = 1 - \sin(42) = 0.33$$

Figure 4: Horizontal/vertical stress ratio during oedometer test

3. PLATE ELEMENTS

3.1 Plate Element

Overview:

1. 3 or 5 noded line elements (for 6-noded or 15-noded element mesh)
2. 3 degrees of freedom per node
3. Plates have:
 - o Axial forces
 - o Shear forces
 - o Bending moments
 - o Hoop forces (axisymmetry)
4. Elastic or elastoplastic behaviour
5. For modelling walls, floors, tunnels

Hinged connection

Rigid connection
(default)

Spring data:

- Stiffness
- Min/Max moment

Rotation
spring

Illustration: Connection.P2D

3.8 Plate Element

Walls – thin wall vs. thick wall

- **Thin wall**
 - Wall thickness $\ll$ wall length
 - No much end-bearing, only friction

→ **Plate element suffices**
- **Thick wall**
 - Wall thickness significant
 - End-bearing capacity needed

→ **Use soil elements with material set representing wall material**

→ **In order to obtain structural forces a plate with fictitious properties may be inserted**

3.9 Plate Element

Walls – thick wall

1. Soil elements with material set representing wall material
2. Difficult to obtain structural forces from soil elements, therefore introduce very flexible plate within the solid wall elements:
 - No influence on deformation: low stiffness, no weight
 - Located in on the neutral line (usually the middle)
 - Tight bonding to the concrete elements: no interfaces

(Illustration: Beam.P2D):

Solid elements: $E_{\text{soil}} = E_{\text{wall}}$, $I = \frac{1}{12} * d^3$, d = wall thickness

Plate element: $EI = E_{\text{soil}}I / x$, choose x large (e.g. 10^6)

$$u_{\text{plate}} = u_{\text{soil}} \rightarrow M_{\text{wall}} = x * M_{\text{plate}}, Q_{\text{wall}} = x * Q_{\text{plate}}$$

Placing a Hinge for free rotation of plates

Can be placed at joint between plate elements – allows for free rotation

Full-height panel support to reinforced soil walls – rigid body rotation of facing

Incremental panel support to reinforced soil walls – bulging type deformation at front end

STRUCTURAL ELEMENTS

4. ANCHOR ELEMENTS

4. Anchor Element

Anchors – fixed-end

- a) To model supports, anchors and struts
 - a) Elasto-plastic spring element
 - b) One end fixed to point in the geometry, other end is fully fixed for displacement
 - c) Positioning at any angle
 - d) Pre-stressing option

Anchors – node-to-node

4.1 Anchor Element

Anchors – material properties

Axial stiffness, EA (for one anchor)

[kN]

Spacing, L_s (out-of-plane distance between anchors)

[m]

Maximum anchor force for compression and tension,

5.2 Anchor Element + Geogrid Element

Ground anchors

1. Combination of node-to-node anchor and geogrid
2. Node-to-node anchor represents anchor rod (free length)
(no interaction with surrounding soil)
3. Geogrid represents grouted part (full interaction with surrounding soil)
4. No interface around grouted part; interface would create unrealistic failure surface
5. Working load conditions only – no pullout
6. If pullout force is known this can be used by limiting anchor rod force

Modeling of soil nails using
geogrid elements

m 2011.0.7663.7305

Total displacements [u]

Maximum value = 261.8 m (Element 901 at Node 7708)

PLAXIS

User name

Indian Institute of Technology Madras

Date

8/7/2012

5.3 Ground anchors

Axial force distribution along fixed length (modelled using geogrid)

Input geometry

Generated mesh

5.4 Ground Anchors: Influence of node numbers along structural elements

Axial forces N (scaled up 0.0500 times)
Maximum value = 27.46 kN/m (Element 1 at Node 90)
Minimum value = 5.532 kN/m (Element 4 at Node 50)

Axial forces M (scaled up 0.0500 times)
Maximum value = 63.79 kN/m (Element 1 at Node 90)
Minimum value = 0.5191 kN/m (Element 68 at Node 10)

STRUCTURAL ELEMENTS

6. INTERFACE ELEMENTS

6.1 Interface Element

Interfaces – material properties

1. Soil-structure interaction
 1. Wall friction
 2. Slip and gapping between soil and structure
2. Soil material properties
 - A. Taken from soil using reduction factor R_{inter}
3. Individual material set for interface possible

Interfaces – soil structure interaction

- Doubling of nodes to (partially) uncouple soil and structural element
- Spring connection between soil nodes and structural nodes
 - Normal spring
 - Shear spring
- Allows for modelling of slip, gapping and closing between soil and structure
- Can also be used between two soil materials

Output:

- Normal stresses
- Shear stresses
- Displacements

Interfaces – material properties

- Soil material properties

Taken from soil using reduction factor R_{inter}

$$\begin{aligned}C_{inter} &= R_{inter} * C_{soil} \\ \tan(\phi_{inter}) &= R_{inter} * \tan(\phi_{soil}) \\ \psi_{inter} &= 0 \text{ for } R_{inter} < 1 \\ &= \psi_{soil} \text{ } R_{inter} = 1 \\ \sigma_{t,inter} &= R_{inter} * \sigma_{t,soil} \\ G_{inter} &= (R_{inter})^2 * G_{soil}\end{aligned}$$

1. Residual reduction factor $R_{inter,res}$ only affects strength, not stiffness
2. Individual material set for interface possible

Interfaces – material properties

1. Residual strength after reaching maximum shear strength
2. Gap closure

6.2 Interface Element

Interfaces – reduction factor

Suggestions for R_{inter} :

- Interaction sand/steel $= R_{inter} \approx 0.6 - 0.7$
- Interaction clay/steel $= R_{inter} \approx 0.5$
- Interaction sand/concrete $= R_{inter} \approx 1.0 - 0.8$
- Interaction clay/concrete $= R_{inter} \approx 1.0 - 0.7$
- Interaction soil/geogrid (**grouted body**) $= R_{inter} \approx 1.0$
(interface may not be required)
- Interaction soil/geotextile $= R_{inter} \approx 0.9 - 0.5$ (foil, textile)

With reference to BS8002:

3.2.6 Design values of wall friction, base friction and undrained wall adhesion

These should be derived from the representative strength determined in accordance with 2.2.8, using the same mobilization factors as for the adjacent soil.

The design value of the friction or adhesion to be mobilized at an interface with the structure should be the lesser of:

- a) the representative value determined by test as described in 2.2.8 if such test results are available; or
- b) 75 % of the design shear strength to be mobilized in the soil itself, that is using:

$$\text{design } \tan \delta = 0.75 \times \text{design } \tan \varphi' \quad (5)$$

$$\text{design } c_w = 0.75 \times \text{design } c_u \quad (6)$$

Interfaces

- Try to omit stress oscillations at corners of stiff structures

Inflexible
corner points,
may cause bad
stress results

Flexible corner
points with
improved stress
results

STRUCTURAL ELEMENTS

7.EMBEDDED BEAM ROW ELEMENTS

Embedded pile row (Embedded Beam Row)

- 3 or 5-noded line element
- Interaction with soil through an interface allowing for skin friction (linear skin resistance distribution)
- End-bearing capacity through spring connection
- Soil can “flow” in between piles
- Available from Plaxis 2D 2012

Embedded pile row - parameters

Embedded pile row - Grout body upper

Material data

Pile shape

Rayleigh damping (dynamics)

Skin resistance

Base resistance

Interface stiffness factors

Embedded pile row – parameters

1. Material data (stiffness E and material weight γ)
2. Pile shape (circular or square, hollow or massive, user-defined)
3. Cross sectional data (area A , moment of inertia I)
4. Out-of-plane spacing
5. Skin resistance at top and bottom of the pile row ($T_{\text{top,max}}$ and $T_{\text{bottom,max}}$)
6. Base resistance (F_{max})
7. Interface stiffness factors
 - Determined by curve fitting on predefined load-displacement curves
 - Default values obtained from the load-displacement curve for a pile in Dutch soil conditions (bored pile in sand, submerged) according to the national annex of Eurocode 7.

GOOD USAGE AND APPLICATION OF STRUCTURAL ELEMENTS

ADDITIONAL INSIGHTS

Plates / Shells - Boundary Conditions

- Rotation fixed at (partly) fixed boundaries – axis of symmetry
- Rotation free at free boundaries

Plates / Shells – Connections

Anchors - Material Properties

Residual strength (Plaxis 2D 2012)

Anchors - Pre-Stressing

- Defined in Staged Construction phase
- Both tension (grout anchor) or compression (strut) possible

Geogrids

1. 3 or 5 noded line element
2. Elastic or elasto-plastic behaviour
3. No flexural rigidity (EI), only axial stiffness (EA)
4. Only allows for tension, not for compression
5. Updated Mesh option relevant

Grouted Anchors

Combination of free length and bonded length

1. **Free length** is modelled using a node-to-node anchors (no interaction with surrounding soil)
2. **Bonded length** is modelled using either as:
 - A. **Geotextile**
 - Full bonding with the soil
 - No interface around grouted part (interface may create unrealistic failure surface)
 - B. **Embedded pile row** (Plaxis 2D 2012 and higher)
 - Allows for slip
 - Allows for soil to move in between anchors (more realistic)

Grouted Anchors - Axial Forces

Geotextile as grout body

$N_{rod} \neq N_{grout}$ due to shared node between anchor, geotextile and soil

Embedded pile row as grout body

Grouted Anchors – Practical Use

Pullout mechanism technically possible with embedded pile row

1. Properties of the steel rod for the beam

2. Linear skin resistance based on cylindrical grout body shape and pull-out strength q_s

$$T_{\text{skin,start}} = T_{\text{skin,end}} = q_s \pi D_{\text{grout}}$$

3. Base resistance set to 0

4. Interface stiffness factor set to default values

Property	Unit	Value

Grouted Anchors – Practical Use

1. **Some practical uncertainties still remains:**
 - **Size and shape of the grout body**
 - **Degree of bonding between grout body and soil**
2. **Alternative: If pull-out force is known this can be used by limiting anchor rod force**

Soil-Structure Interaction: Interface Elements

1. Interface elements handle normal and shear behaviour

- Linear elastic perfectly plastic behaviour
- Shear strength defined according MC criterion (slipping)
- Tension cut-off (gapping)

Interfaces – Material Properties

Soil material properties

1. Taken by default from soil using reduction factor R_{inter}

$$\begin{aligned} C_{inter} &= R_{inter} * C_{soil} \\ \tan(\varphi_{inter}) &= R_{inter} * \tan(\varphi_{soil}) \end{aligned}$$

$$\begin{aligned} \psi_{inter} &= 0 \text{ for } R_{inter} < 1 \\ &= \psi_{soil} \text{ } R_{inter} = 1 \end{aligned}$$

$$\sigma_{t,inter} = R_{inter} * \sigma_{t,soil}$$

$$G_{inter} = (R_{inter})^2 * G_{soil}$$

2. Residual reduction factor $R_{inter,res}$ only affects strength, not stiffness.
3. Individual material set for interface possible

Interfaces – Material Properties

Additional features

- Residual strength when reaching maximum shear strength
- Gap closure

- 3D Example
- Comparison with in-situ measurements
- Note on ϕ -c-reduction

NUMERICAL ANALYSIS OF DEEP EXCAVATIONS

involves modelling of

- various excavation stages
- interaction wall / soil > interface elements
- changes in groundwater level
- struts or anchors (including load transfer to soil)
- adjacent structures (buildings, tunnels, piles, ...)

requires advanced constitutive model because

- stress paths in soil are not monotonic (significant change in stress path direction)
 - primary loading and unloading / reloading occurs in different parts of the domain analysed
 - some areas will experience large strains with significant plastic deformations, others will be in the very small strain range
- > simple elastic - perfectly plastic models not sufficient

**2D model
sufficient**

3D model preferable, but 2D approximation possible

INTRODUCTION

3D model required

Th.Voit, 2016

HYDRAULIC CONDITIONS

■ Setting of new hydraulic conditions

- Consider each individual case carefully
- Select the relevant situation: undrained, drained or consolidation, it may be different for different materials

■ Specifying pore pressure distributions

- **General phreatic level**
> applies to all clusters that have not been separately defined
- **Cluster phreatic level** > applies to one specific cluster
- **Cluster dry** > makes a specific cluster dry
- **Interpolate** > interpolates pore pressures between clusters above and below
- **User-defined pore pressure**
> specify pore pressure at reference level and the rate of increase in the y-direction
- **Groundwater flow calculation** > gives the steady-state solution

HYDRAULIC CONDITIONS

Groundwater flow calculations

- Plate elements are permeable
- Interface elements are impermeable (unless deactivated in the groundwater flow calculation)

HYDRAULIC CONDITIONS

Dewatering

Z-shape phreatic level gives wrong results:

- No equilibrium in horizontal water pressures:
 - Local peak stresses
 - Local peak strains
 - Non-physical horizontal displacements
 - Non-physical excess pore pressures
- Possible incorrect water pressure acting on wall

3D EXAMPLE

EXCAVATION OF BUILDING PIT (MC-Model)

PLAXIS ADVANCED COURSE

INTRODUCTION

A building pit was constructed in the south of the Netherlands. The pit is 15 m deep and 30 m wide. A diaphragm wall is constructed using 60 cm diameter bored piles; the wall is anchored by two rows of pre-stressed ground anchors. In this exercise the construction of this building pit is simulated and the deformation and bending moments of the wall are evaluated.

The upper 40 m of the subsoil consists of a more or less homogeneous layer of medium dense fine sand with a unit weight of 18 kN/m^3 . Triaxial test data of a representative soil sample is given in Figure 2. Underneath this layer there is very stiff layer of gravel, which is not to be included in the model. The groundwater table is very deep and does not play a role in this analysis.

AIMS

- Determination of soil stiffness parameters
- Using interface elements
- Using ground anchors
- Pre-stressing of anchors
- Combination of structural elements

Figure 1: Geometry for tied-back excavation.

DETERMINATION OF STIFFNESS & STRENGTH PROPERTIES (SAND)

Use the Mohr-Coulomb model and extract model parameters for the sand layer from the triaxial test data. Concerning stiffness behaviour, take into account the fact that the excavation involves **unloading rather than primary loading**. It is suggested to divide the sub-soil into three regions: Top Sand (0 m → -15 m), Middle Sand (-15 m → -25 m) and Lower Sand (-25 m → -35 m). This allows for the input of an average stiffness in each individual region. As the simple Mohr-Coulomb model cannot take into account the stress-dependency of the stiffness, the input of an average stiffness per region, by the user, is the next best option to enhance the model. Please note there are other models (HS and SS model) available in PLAXIS that take into account the stress-dependency of the soil stiffness. These advanced models will be introduced in a later exercise. The soil parameters can be entered into Table 1.

Figure 2: Mohr-Coulomb model for the sand layer.

GEOMETRY AND MATERIAL PROPERTIES INPUT

Start a new project

Enter general settings

- Accept the default values in the Project tab sheet of the *General settings (15-node elements)*. For the dimensions see Figure 3.

Figure 3: General settings, tab sheet dimensions.

Enter GEOMETRY, PLATE, interfaces, anchors, and geotextiles

- Start by using the borehole tool  to define the virgin soil conditions.
 - Enter the material properties for the three soil data sets, as determined in the first table of this exercise.
 - After entering all properties for the three soil types, drag and drop the properties to the graph of the soil column on the left hand side.
 - Set the *Head* in the borehole to -55 m.
 - Click the *Structures* tab to proceed with the input of structural elements in the Structures mode.
- 
- Enter the geometry as proposed in Figure 4

Figure 4: Geometry of the model

- Click the *Create structure* button  in the side toolbar and select the *Create Plate*  *Create plate* option to introduce the diaphragm wall.
- Click the *Create structure* button again and select the *Create geogrid*  *Create geogrid* option to introduce the two geotextile elements that represent the grout body.
- Right-click the plate representing the diaphragm wall. Point to *Create* and click on the *Positive interface* option in the appearing menu (Figure 5). In the same way assign a negative interface as well.

Figure 5: Interface assignment to existing geometry

- Click the *Create structure* button again and select the *create node to node anchor* option to introduce the two anchors. These anchors connect the beginning of the grout-body to the wall.
- Enter material properties for the plates, anchors and `geogrids` as indicated in Table 2, Table 3 and Table 4. After entering all properties, assign the appropriate properties to the structures.

Table 2: Properties of the diaphragm wall (plate)

Parameter	Symbol	Diaphragm wall	Unit
Material Model	Model	Linear Elastic	-
Normal stiffness	EA	$8.0 \cdot 10^7$	kN/m
Flexural rigidity	EI	$1.5 \cdot 10^6$	kNm ² /m
Weight	w	8.0	kN/m/m
Poisson's ratio	ν	0.0	-

Table 3: Properties of the anchor rod (node-to-node anchors).

Parameter	Symbol	Anchor rod	Unit
Material Model	Model	Elastic	-
Normal stiffness	EA	$2.0 \cdot 10^5$	kN/m
Spacing	L_s	1.0	m

Table 4: Property of the grout body (geogrid).

Parameter	Symbol	Grout body	Unit
Normal stiffness	EA	$2.0 \cdot 10^5$	kN/m

MESH GENERATION

- Proceed to the *Mesh* mode. Generate the mesh and use the default option for the Element distribution (medium).
- View the mesh. The resulting mesh is shown in Figure 6.

Figure 6: Medium Finite Element mesh

- Select the *Clusters*  around the diaphragm wall and press *Refine Clusters*  button. Generate the mesh again. This will result in a refinement around the selected *Clusters* as shown in Figure 7.

Figure 7: Refined Finite Element mesh

WATER CONDITIONS

- As the phreatic surface is located below the deep sand 2 layer, the generation of pore pressures can be skipped.

CALCULATION

- Click on the *Staged construction* tab to proceed with the definition of the calculation phases.
- In the Phases explorer the *Initial phase* is already introduced. Double click the *Initial phase* to check if the calculation type is *KO procedure*.

Make sure all the soil volumes are active and all the structural elements are inactive.

Construction process

The entire construction process consists of five phases. Define the phases, as shown graphically below. For each phase, use *plastic* for the *calculation type* and *Staged construction* for the *loading type*.

- In the first phase (Figure 10) the diaphragm wall is activated and the first excavation takes place. Note that though the interfaces along the wall are activated automatically with the activation of the wall.
- In the second phase (Figure 11), a new option is used, namely the pre-stressing of anchors.
- First the grout-body (the geogrid) is switched on by right clicking on the 'geogrid' element and activating it. The element will appear in yellow as soon as it is switched on. The light grey color indicates non-active elements.
- Now the grout-body is active and the anchor element needs to be pre-stressed. In the Selection explorer set the Adjust prestress parameter to true and assign a pre-stress force of 300kN (Figure 8). The letter P indicates that a pre-stress force will be active in the anchor.

Create the remaining phases, as indicated in Figure 12, Figure 13 and Figure 14. Select some nodes for the load displacement curves (e.g. top of wall).

Figure 8: Selection explorer

Hint: A pre-stress force is exactly matched at the end of a finished staged construction calculation and turned into an anchor force. In successive calculation phases the force is considered to be just an anchor force and can therefore further increase or decrease, depending on the development of the surrounding stresses and forces.

- Start the Calculation. 

Figure 9: Initial conditions, diaphragm wall and anchors are not active.

Figure 10: Phase 1, excavation and activation of the diaphragm wall.

Figure 11: Phase 2, activation of the anchor and geotextile (grouting). Pre-stressing of the anchor to a value of 300 kN/m.

Figure 12: Phase 3, excavation of the second part.

Figure 13: Phase 4, activation of the second anchor and geotextile (grouting). Pre-stressing of the anchor to a value of 300 kN/m.

Figure 14: Phase 5, excavation of the third part

INSPECT OUTPUT

By double clicking on the node-to-node anchors, Plaxis will present a box, in which the stress in the anchor may be inspected.

Figure 15: Deformed mesh (MC-model with E_{50} - modulus)

Figure 16: Deformed mesh (MC-model with E_{ur} - modulus)

Figure 15: Sole heave after the last excavation step

Figure 16: Bending moments after the last excavation step

STIFFNESS PARAMETERS

Since excavation is considered in this exercise, the input of Young's modulus E should be based on unloading, rather than on primary loading.

$\sigma_3 = 100 \text{ kPa}$ (corresponds with reference pressure, $E_{50} = E_{50}^{\text{ref}}$)

$$E_{50} = \frac{\Delta\sigma_v}{\Delta\epsilon_v} = \frac{135}{0,675\%} = 2,0 \cdot 10^4 \text{ kN/m}^2 \quad \text{assume } E_{ur} \approx 4 E_{50}$$

For improved modelling, three regions are distinguished, for each individual layer an average stiffness is determined by using:

$$E_{50} = E_{50}^{\text{ref}} \sqrt{\frac{\sigma_3}{p_{\text{ref}}}} \quad E_{50} \approx E_{\text{load}} \rightarrow E_{ur} \approx E_{\text{unload}}$$

We distinguish:

Top layer (from top to -15 m)

Middle layer (from -15 m to -25 m)

Lower layer (from -25 m to -35 m)

Top layer:

$$\sigma_3 = \text{depth} \cdot \gamma_{\text{soil}} \cdot K_0$$

σ_3 = average horizontal stress (reference point at -7.5 m)

$$\sigma_3 = 7.5 \cdot 18 \cdot (1 - \sin\varphi) = \mathbf{58 \text{ kPa}}$$

$$E_{50}^{\text{top}} = 2,0 \cdot 10^4 \sqrt{\frac{58}{100}} \sim 1,5 \cdot 10^4 \text{ kPa}$$

$$E_{ur}^{\text{top}} \approx 4 \cdot E_{50}^{\text{top}} = 6,0 \cdot 10^4 \text{ kPa}$$

Middle layer:

$$\sigma_3 = 20 \cdot 18 \cdot (1 - \sin\varphi) = \mathbf{153 \text{ kPa}}$$

$$E_{50}^{\text{middle}} = 2,0 \cdot 10^4 \sqrt{\frac{153}{100}} \sim 2,5 \cdot 10^4 \text{ kPa}$$

$$E_{ur}^{\text{middle}} \approx 4 \cdot E_{50}^{\text{middle}} = 1,0 \cdot 10^5 \text{ kPa}$$

Lower layer:

$$\sigma_3 = 30 \cdot 18 \cdot (1 - \sin\varphi) = \mathbf{230 \text{ kPa}}$$

$$E_{50}^{\text{bottom}} = 2,0 \cdot 10^4 \sqrt{\frac{230}{100}} \sim 3,0 \cdot 10^4 \text{ kPa}$$

$$E_{ur}^{\text{bottom}} \approx 4 \cdot E_{50}^{\text{bottom}} = 1,2 \cdot 10^5 \text{ kPa}$$

Assume for all layers $\nu = 0.33$.

EXCAVATION OF BUILDING PIT (HS-Model and HSS-Model)

PLAXIS ADVANCED COURSE

INTRODUCTION

In the next exercise the geometry from 'Excavation of building pit (MC-Model)' is used. Instead of the Mohr-Coulomb model, the Hardening Soil and the Hardening Soil Small model is used.

A building pit was constructed in the south of the Netherlands. The pit is 15 m deep and 30 m wide. A diaphragm wall is constructed using 60 cm diameter bored piles; the wall is anchored by two rows of pre-stressed ground anchors. In this exercise the construction of this building pit is simulated and the deformation and bending moments of the wall are evaluated.

The upper 40 m of the subsoil consists of a more or less homogeneous layer of medium dense fine sand with a unit weight of 18 kN/m^3 . Triaxial test data of a representative soil sample is given in the exercise 'Excavation of building pit in (MC-Model)'. The groundwater table is very deep and does not play a role in this analysis.

GEOMETRY INPUT

- Select the existing project of the 'Excavation of building pit (MC-Model)' exercise.
- From the File menu select Save As and save the existing project under a new file name.

GEOMETRY INPUT – HS MODEL

- Modify the material properties by selecting the item Soils & Interfaces from the Materials menu. Use the material properties as given in Table 1. Assign the Sand material set to all soil clusters.

Figure 1: Geometry for tied-back excavation.

Table 1: Soil material set parameters for HS-model.

Parameter	Symbol	Top/Middle/ Lower sand	Deep sand 1	Deep sand 2	Unit
Material model	Model	HS-model	HS-model	HS-model	-
Type of behaviour	Type	drained	drained	drained	-

CALCULATION

Construction process

The entire construction process consists of five phases. Define the phases, as shown graphically below. For each phase, use the *Plastic calculation, Staged construction*.

Create the remaining phases, as indicated in Figure 2, Figure 3, Figure 4, Figure 5, Figure 6 and Figure 7. Select some nodes for the load displacement curves (e.g. top of wall).

Figure 2: Initial conditions, diaphragm wall and anchors are not active.

Figure 3: Phase 1, excavation and activation of the diaphragm wall.

Figure 4: Phase 2, activation of the anchor and geotextile (grouting). Pre-stressing of the anchor to a value of 300 kN/m.

Figure 5: Phase 3, excavation of the second part.

Figure 6: Phase 4, activation of the second anchor and geotextile (grouting). Pre-stressing of the anchor to a value of 300 kN/m.

Figure 7: Phase 5, excavation of the third part.

GEOMETRY INPUT - CHANGE MATERIAL (HSS MODEL)

- Modify the material properties by selecting the item Soils & Interfaces from the Materials menu. Use the material properties as given in Table 2. Assign the Sand material set to all soil clusters.

Table 2: Soil material set parameters for HSS-model.

Parameter	Symbol	Top sand / Middle sand / Lower sand / Deep sand 1 + 2	Unit

Modelling of Groundwater in Plaxis

PART A: INTRODUCTION

Groundwater Analysis and Conditions

- A. Geotechnical problems are related to groundwater
- B. Two extreme conditions of porewater response are normally considered, they are:
 - 1. Drained
 - 2. Undrained (Method A, B & C)
- C. Real soil behaviour is related to time , i.e. transient, with the porewater pressure being dependent on imposed:
 - 1. Permeability
 - 2. Rate of loading
 - 3. Hydraulic (Flow) boundary conditions
- D. The interstitial voids of the soil skeleton can be fully or partially filled with pore fluid and therefore effective stresses are influenced by this action
- E. This lecture will look into the following issues:
 - 1. The setup of pore pressures in PLAXIS
 - 2. Input parameters
 - 3. Some examples of groundwater regimes

Modelling of Groundwater in Plaxis

PART B: DEFINITIONS OF PORE PRESSURES IN PLAXIS

A. DEFINITIONS AND MODES

A. Calculation Type (Staged Construction Mode)

1. Ground Water Flow Only
2. Consolidation (based on P_{excess} ONLY)
3. Fully Coupled Flow-Deformation Consolidation (based on Total PWP ie P_{active})

B. Definition of Pore Water Pressure Terms in Plaxis

1. P_{active} - Active State Pore Pressures (idea of Total Pore Water Pressure)
2. P_{water} - Pore Water Pressures ($P_{\text{steady}} + P_{\text{excess}}$)
3. P_{steady} - Steady State Pore Pressures (Background)
4. P_{excess} - Excess Pore Pressures

GROUNDWATER FLOW ONLY MODE

Groundwater Flow mode:

- Similar to PlaxFlow but with huge improvements in the kernel (see Galavi, 2010)
- All functionalities of PlaxFlow rewritten in PLAXIS code (new)
- Steady state groundwater flow
- Transient groundwater flow (ONLY POSSIBLE IN THIS MODE)
- All types of boundary conditions
- New features in wells and drains
- Faster calculation (new)

PLASTIC OR CONSOLIDATION TYPE

Name	Value
General	
ID	Phase_1 CLASSICAL CONSOLIDATION [Phase_1]
Start from phase	Initial phase
Calculation type	Consolidation

- A. Consolidation analysis ON Total PP
- B. Transient groundwater flow analysis is implied in the calculations

KERNEL

9.3.6 PORE PRESSURES

Pore pressures are the quantities that relate to the stress in the pores of the material. The pores in soil are usually filled with a mixture of water and air. In most cases, stresses and pore pressures in the soil are negative (pressure). However, due to capillary action or undrained unloading, pore pressures may become positive (tension), which is denoted as suction.

- PLAXIS distinguishes between different types of pore pressures and related quantities. It is important to understand the differences between these quantities in order to properly interpret the results from a PLAXIS calculation.

Total stresses are divided into effective stresses, σ' , and active pore pressures, p_{active} .

$$\sigma = \sigma' + p_{active}$$

Active pore pressures are defined as the effective saturation, S_{eff} , times the pore water pressures, p_{water} .

$$p_{active} = S_{eff} \cdot p_{water}$$

Effective degree of saturation: $S_{eff} = (S - S_{res}) / (S_{sat} - S_{res})$

Degree of saturation: S

Residual degree of saturation: S_{res}

Pore water pressure differs from active pore pressure when the degree of saturation is less than unity, which is usually the case above the phreatic level. Below the phreatic level p_{active} and p_{water} are generally equal.

PORE WATER PRESSURE

P_{water}

Total stresses are divided into effective stresses and pore pressures. Pore pressures are composed of steady-state pore pressures and excess pore pressures, including suction. Since decades, PLAXIS uses the term 'active pore pressure' to denote the contribution of the pore stresses in the total stresses. In the context of unsaturated soil behaviour, active pore pressure is defined as:

Active pore pressure: $p_{\text{active}} = S_{\text{eff}}(p_{\text{steady}} + p_{\text{excess}}) = S_{\text{eff}} p_w$

Pore water pressure: $p_{\text{water}} = p_{\text{steady}} + p_{\text{excess}}$

Note that for fully saturated soil the 'active pore pressure' is equal to the 'pore water pressure', but there is a clear difference in the unsaturated zone.

As an alternative to the pore water pressure, p_{water} , the groundwater head, h , can be viewed:

$$h = z - \frac{p_{\text{water}}}{\gamma_w}$$

where z is the vertical coordinate and γ_w is the unit weight of water. In the pore water pressure a further distinction is made between steady state pore pressure, p_{steady} , and excess pore pressure, p_{excess} .

$$p_{\text{water}} = p_{\text{steady}} + p_{\text{excess}}$$

where steady-state pore pressure is the steady-state or long term part of pore pressure, which is supposed to be input data for a deformation analysis.

Excess pore pressure is the result from undrained behaviour (Undrained (A) or (B), or low-permeable materials), and is affected by stress changes due to loading or unloading, a (sudden) change in hydraulic conditions and consolidation.

STEADY-STATE AND EXCESS PORE PRESSURE

P_{steady} P_{excess}

Steady-state pore pressure: p_{steady}

- Input for a deformation analysis Plastic Drained or Undrained Analysis
- Direct generation based on phreatic levels and cluster-related pore pressure distribution
- Or, calculated from steady-state groundwater flow calculation GWF- STEADYFLOW

Excess pore pressure: p_{excess}

- Result from undrained behaviour (*Undrained (A)* or (*B*)) and K_w/n from Table C.1
- Affected by loading, a (sudden) change in hydraulic conditions and consolidation.
- In the case of a fully coupled flow-deformation analysis, p_{steady} is calculated from a preliminary steady-state groundwater flow calculation using the hydraulic boundary conditions at the end of the calculation phase. This enables the calculation and output of p_{excess} for a fully coupled analysis in all steps. $p_{\text{excess}} = p_{\text{water}} - p_{\text{steady}}$.

Consolidation process is dissipation of P_{active} or P_{excess} to P_{steady} values in the long-term condition

SATURATION AND SUCTION

SATURATION

Effective degree of saturation: $S_{eff} = (S - S_{res}) / (S_{sat} - S_{res})$

Degree of saturation: S

Residual degree of saturation: S_{res}

Saturated degree of saturation: S_{sat} (usually 1.0)

- There is a relationship between the (effective) degree of saturation (S or S_{eff}) and the suction in the unsaturated zone, which depends on the selected soil-water retention curve in the material data set. By default, the data set for 'fine sand' is selected. **SWRC (OR SWCC OR RC) = SATURATION – SUCTION RELATIONSHIP**

SUCTION

The term 'suction' is used to denote any positive value of pore water stress (pore water tension):

Suction: Tension component in p_{water} : $Suction = Max(p_{water}, 0)$

- Suction could be a result of a positive component in p_{steady} as well as p_{excess} , but it is evaluated from the sum of both. **Include Steady (capillary action) and Excess_PP components (undrained unloading)**

Effective suction: $Suction_{eff} = S_{eff} Suction$

- When multiplied by the tangent of the friction angle, this quantity gives a kind of 'artificial cohesion' in the soil. **This is known as the apparent cohesion**

Similar in concept to Prof Fredlund's strength model $C_a = (u_a - u_w) \tan \phi_b = S_{eff} \cdot \tan \phi$

TERZAGHI OR BISHOP EFFECTIVE STRESS

Terzaghi Effective Stress (**only for Saturated Soil with pressure or suction**)

Effective stress: σ' (stress in the soil skeleton)

Total stress: $\sigma = \sigma' + p_{active}$

Terzaghi's effective stress: $\sigma' = \sigma - p_{active}$

- Terzaghi's definition of effective stress applies to saturated soils.

Bishop Effective Stress (**only for Saturated/Unsaturated Soil with pressure or suction**)

Bishop's stress: $\sigma' = \sigma - p_a + \chi(p_a - p_{water})$

Atmospheric pressure: p_a (100 kPa, but in PLAXIS taken as the zero reference level)

Matric suction coefficient: χ

S-eff = Effective Degree of Saturation

In PLAXIS, p_a is assumed to be 0 and χ is supposed to be equal to S_{eff} , so Bishop's stress in PLAXIS:

$$\sigma' = \sigma - S_{eff} \cdot (p_{steady} + p_{excess}) = \sigma - p_{active}$$

- When the soil reaches full saturation ($S_{eff} = 1$), Bishop's stress coincides with Terzaghi's effective stress.
- Using Bishop's effective stress as a basis for all calculations, distinction can still be made between conventional calculations (fully saturated or dry materials) and calculations in which unsaturated soil behaviour is taken into account.
- The aforementioned distinction can be made by ignoring suction or allowing suction.

Modelling of Groundwater in Plaxis

PART C: GENERATION OF POREWATER PRESSURES

GENERATION OF STEADY-STATE PORE PRESSURES

Steady-state (Background) pore pressures can be generated by:

- A. Phreatic and Cluster Approach (Hydrostatic)
- B. Groundwater Flow Analysis

PHREATIC AND CLUSTER APPROACH

GENERATION OF STEADY-STATE PRESSURES

PHREATIC AND CLUSTER APPROACH

A. Phreatic Level

1. General Phreatic Level
2. Cluster Phreatic Level

B. Cluster Pore Pressure Distribution

1. Interpolation (Adjacent to clusters or phreatic lines)
2. Cluster Dry
3. User-defined Pore Pressure Distribution (by Customised BH)

C1. PHREATIC LINE

- a) Porewater pressures are hydrostatic
- b) Calculated based on $\gamma_w \cdot h$
- c) Simple situations (water-table is horizontal)
- d) No flow
- e) For cases, i.e. simple excavations, foundations or embankments

Extraction
or Infiltration
well

Figure 5.42 Well definition in the *Selection explorer*

The minimum possible head in the well. When the groundwater head reduces below the h_{min} level no further extraction will occur. As a habit, h_{min} may be set equal to the bottom level of the well in the ground.

- Drains are lines where Excess PP are set to reduce to the specified head h . These are relevant only to GW Flow, Consolidation or Fully Coupled Analysis
- Normal drains setting will cause Excess PP to reduce to given head h , usually set at hydrostatic value. PP lower than given head are not affected (ie it works only for compressive Excess PP)
- Vacuum drains allow drains to reduce Excess PP to below atmospheric pressures (tensile Excess PP). The value of h is set to -ve value usually to a maximum of -10m (-100 kPa). Real drains can only achieve between -60 and -80 kPa

Groundwater Flow Analysis

GENERATION OF STEADY-STATE PRESSURES

GROUNDWATER FLOW ANALYSIS OPTIONS

1. Steady-state Pore Pressure Generation based on Groundwater Flow Calculation
 - PLASTIC CALCULATION TYPE
 - CONSOLIDATION CALCULATION TYPE
2. Transient-state groundwater flow
 - IMPLIED IN FULL-COUPLED FLOW DEFORMATION ANALYSIS
 - POSSIBLE TO PERFORM THIS ANALYSIS IN “PURE” GWF MODE

GROUNDWATER FLOW: STEADY STATE

Calculation based on setup of:

1. Boundary conditions:
 - a) Prescribed water levels (constant)
 - b) Closed flow boundaries (bottom, axis of symmetry)
 - c) Wells and drains (constant)
 - d) Interface elements (on=impermeable, off=permeable)
 - e) Inflow / outflow (constant)
2. Soil permeabilities of layers
3. Phreatic level in the soil is being calculated for $t=\infty$

GROUNDWATER FLOW: TRANSIENT-STATE

Transient groundwater flow:

1. Boundary conditions
 - a) Prescribed water levels (changing with time)
 - b) Closed flow boundaries (bottom, axis of symmetry)
 - c) Wells and drains (changing with time)
 - d) Interface elements (on=impermeable, off=permeable)
 - e) Inflow / outflow (changing with time)
2. Flow field changes in time:
 - a) Constantly changing natural water conditions
 - b) Relatively fast building process, pumping, wells
3. Embankments with river changes, tidal change
4. Reservoir impoundment and drawdown
5. Precipitation problems

Maximum value: 1.14100E+07 (a) (b) (c) (d) (e) (f) (g) (h) (i) (j) (k) (l) (m) (n) (o) (p) (q) (r) (s) (t) (u) (v) (w) (x) (y) (z) (aa) (ab) (ac) (ad) (ae) (af) (ag) (ah) (ai) (aj) (ak) (al) (am) (an) (ao) (ap) (aq) (ar) (as) (at) (au) (av) (aw) (ax) (ay) (az) (ba) (bb) (bc) (bd) (be) (bf) (bg) (bh) (bi) (bj) (bk) (bl) (bm) (bn) (bo) (bp) (bq) (br) (bs) (bt) (bu) (bv) (bw) (bx) (by) (bz) (ca) (cb) (cc) (cd) (ce) (cf) (cg) (ch) (ci) (cj) (ck) (cl) (cm) (cn) (co) (cp) (cq) (cr) (cs) (ct) (cu) (cv) (cw) (cx) (cy) (cz) (da) (db) (dc) (dd) (de) (df) (dg) (dh) (di) (dj) (dk) (dl) (dm) (dn) (do) (dp) (dq) (dr) (ds) (dt) (du) (dv) (dw) (dx) (dy) (dz) (ea) (eb) (ec) (ed) (ee) (ef) (eg) (eh) (ei) (ej) (ek) (el) (em) (en) (eo) (ep) (eq) (er) (es) (et) (eu) (ev) (ew) (ex) (ey) (ez) (fa) (fb) (fc) (fd) (fe) (ff) (fg) (fh) (fi) (fj) (fk) (fl) (fm) (fn) (fo) (fp) (fq) (fr) (fs) (ft) (fu) (fv) (fw) (fx) (fy) (fz) (ga) (gb) (gc) (gd) (ge) (gf) (gg) (gh) (gi) (gj) (gk) (gl) (gm) (gn) (go) (gp) (gq) (gr) (gs) (gt) (gu) (gv) (gw) (gx) (gy) (gz) (ha) (hb) (hc) (hd) (he) (hf) (hg) (hh) (hi) (hj) (hk) (hl) (hm) (hn) (ho) (hp) (hq) (hr) (hs) (ht) (hu) (hv) (hw) (hx) (hy) (hz) (ia) (ib) (ic) (id) (ie) (if) (ig) (ih) (ii) (ij) (ik) (il) (im) (in) (io) (ip) (iq) (ir) (is) (it) (iu) (iv) (iw) (ix) (iy) (iz) (ja) (jb) (jc) (jd) (je) (jf) (jg) (jh) (ji) (jj) (jk) (jl) (jm) (jn) (jo) (jp) (jq) (jr) (js) (jt) (ju) (jv) (jw) (jx) (jy) (jz) (ka) (kb) (kc) (kd) (ke) (kf) (kg) (kh) (ki) (kj) (kk) (kl) (km) (kn) (ko) (kp) (kq) (kr) (ks) (kt) (ku) (kv) (kw) (kx) (ky) (kz) (la) (lb) (lc) (ld) (le) (lf) (lg) (lh) (li) (lj) (lk) (ll) (lm) (ln) (lo) (lp) (lq) (lr) (ls) (lt) (lu) (lv) (lw) (lx) (ly) (lz) (ma) (mb) (mc) (md) (me) (mf) (mg) (mh) (mi) (mj) (mk) (ml) (mm) (mn) (mo) (mp) (mq) (mr) (ms) (mt) (mu) (mv) (mw) (mx) (my) (mz) (na) (nb) (nc) (nd) (ne) (nf) (ng) (nh) (ni) (nj) (nk) (nl) (nm) (nn) (no) (np) (nq) (nr) (ns) (nt) (nu) (nv) (nw) (nx) (ny) (nz) (oa) (ob) (oc) (od) (oe) (of) (og) (oh) (oi) (oj) (ok) (ol) (om) (on) (oo) (op) (oq) (or) (os) (ot) (ou) (ov) (ow) (ox) (oy) (oz) (pa) (pb) (pc) (pd) (pe) (pf) (pg) (ph) (pi) (pj) (pk) (pl) (pm) (pn) (po) (pp) (pq) (pr) (ps) (pt) (pu) (pv) (pw) (px) (py) (pz) (qa) (qb) (qc) (qd) (qe) (qf) (qg) (qh) (qi) (qj) (qk) (ql) (qm) (qn) (qo) (qp) (qq) (qr) (qs) (qt) (qu) (qv) (qw) (qx) (qy) (qz) (ra) (rb) (rc) (rd) (re) (rf) (rg) (rh) (ri) (rj) (rk) (rl) (rm) (rn) (ro) (rp) (rq) (rr) (rs) (rt) (ru) (rv) (rw) (rx) (ry) (rz) (sa) (sb) (sc) (sd) (se) (sf) (sg) (sh) (si) (sj) (sk) (sl) (sm) (sn) (so) (sp) (sq) (sr) (ss) (st) (su) (sv) (sw) (sx) (sy) (sz) (ta) (tb) (tc) (td) (te) (tf) (tg) (th) (ti) (tj) (tk) (tl) (tm) (tn) (to) (tp) (tq) (tr) (ts) (tt) (tu) (tv) (tw) (tx) (ty) (tz) (ua) (ub) (uc) (ud) (ue) (uf) (ug) (uh) (ui) (uj) (uk) (ul) (um) (un) (uo) (up) (uq) (ur) (us) (ut) (uu) (uv) (uw) (ux) (uy) (uz) (va) (vb) (vc) (vd) (ve) (vf) (vg) (vh) (vi) (vj) (vk) (vl) (vm) (vn) (vo) (vp) (vq) (vr) (vs) (vt) (vu) (vv) (vw) (vx) (vy) (vz) (wa) (wb) (wc) (wd) (we) (wf) (wg) (wh) (wi) (wj) (wk) (wl) (wm) (wn) (wo) (wp) (wq) (wr) (ws) (wt) (wu) (wv) (ww) (wx) (wy) (wz) (xa) (xb) (xc) (xd) (xe) (xf) (xg) (xh) (xi) (xj) (xk) (xl) (xm) (xn) (xo) (xp) (xq) (xr) (xs) (xt) (xu) (xv) (xw) (xx) (xy) (xz) (ya) (yb) (yc) (yd) (ye) (yf) (yg) (yh) (yi) (yj) (yk) (yl) (ym) (yn) (yo) (yp) (yq) (yr) (ys) (yt) (yu) (yv) (yw) (yx) (yy) (yz) (za) (zb) (zc) (zd) (ze) (zf) (zg) (zh) (zi) (zj) (zk) (zl) (zm) (zn) (zo) (zp) (zq) (zr) (zs) (zt) (zu) (zv) (zw) (zx) (zy) (zz)

RESULTS – GROUNDWATER HEAD

Keywords: *depression, mood, stress, coping, self-esteem, self-efficacy, social support, health, well-being, quality of life*

SOME POINTS: FINITE ELEMENT MODELING

1. GWF calculation generally needs finer mesh than deformation analysis
2. GWF calculation generally needs larger number of steps than deformation analysis
3. GWF calculation usually converges, but can be problematic when:
 - a) Mesh is too coarse
 - b) Elements are distorted
 - c) Large differences in permeability of adjacent layers

SOME POINTS- FINITE ELEMENT MODELING

1. Qualitative evaluation:

- Flow field
- Location of phreatic line

2. Quantitative evaluation:

- Heads, pore pressures compared to hydrostatic,
- Compare with measurements or field experience

Modelling of Groundwater in Plaxis

PART D: HYDRAULIC MODELS IN PLAXIS

Groundwater flow – flow in unsaturated soil

Water content and permeability in unsaturated zone

$$k = k_{rel} k_{sat}, \quad k_{rel} = f(h_p, S)$$

$$S(h) = \frac{\theta(h_p)}{n}$$

$$h_p = \Psi \Rightarrow \text{pressure head}$$

Groundwater flow – flow in unsaturated soil

A. Linear Model

$$k_{rel} = \begin{cases} 1 & h_p > 0 & \text{Saturated} \\ 1 - mh_p & 0 > h_p > \beta & \text{Partially saturated} \\ \varepsilon & h_p < \beta & \text{Dry} \end{cases}$$

For numerical stability

$$\beta > \frac{1}{3} \frac{\sqrt{A_e}}{N_{int}}$$

Groundwater flow – flow in unsaturated soil

Soil Water Characteristic Curve (SWRC or RC)

Groundwater flow – flow in unsaturated soil

van Genuchten model

$$S(h_p) = S_{\text{res}} + (S_{\text{sat}} - S_{\text{res}}) \left(1 + (g_a |h_p|)^{g_n} \right)^{\frac{1-g_n}{g_n}}$$

$$k_{\text{rel}}(S) = (S_e)^{g_l} \left(1 - \left(1 - S_e^{\left(\frac{g_n}{g_n - 1} \right)} \right)^{\left(\frac{g_n - 1}{g_n} \right)} \right)^2$$

with

$$S_e = \frac{S - S_{\text{res}}}{S_{\text{sat}} - S_{\text{res}}}$$

$S_{\text{sat}}, S_{\text{res}}$: saturated and residual saturation

g_a, g_n and g_l : curve fitting parameters

Groundwater flow – flow in unsaturated soil

Approximate van Genuchten model

$$S(h_p) = \begin{cases} 1 & \text{if } h_p \geq 0 \\ 1 + \frac{h_p}{|h_{ps}|} & \text{if } h_{ps} < h_p < 0 \\ 0 & \text{if } h_p \leq h_{ps} \end{cases}$$

Linear in Saturation

$$k_{rel}(h_p) = \begin{cases} 1 & \text{if } h_p \geq 0 \\ 10^{\frac{4h_p}{|h_{pk}|}} & \text{if } h_{pk} < h_p < 0 \\ 10^{-4} & \text{if } h_p \leq h_{pk} \end{cases}$$

Log-linear in Permeability

h_{ps} : length of partially saturated zone under hydrostatic conditions

h_{pk} : pressure head at $k_{rel}=10^{-4}$

Groundwater flow - material data sets

A. Parameters:

1. Permeabilities (k_x , k_y)
2. Void ratio (to calculate storage)
3. Elastic storage coefficient
(The volume of water that a unit volume of saturated soil loses due to a unit reduction in the applied water head)
4. Maximum unsaturated zone height

A. Soil classification

1. Particle fractions
2. Predefined series (Staring, Hypres, USDA) with Van Genuchten and Approx. van Genuchten parameters.
3. User-defined

Groundwater flow - material data sets

Property	Unit	Value

Seepage and Fully
Coupled Flow
Consolidation
analysis

Modelling of Groundwater in Plaxis

PART E: EXCAVATION EXAMPLES

GWT LOWERING BY STEADY STATE SEEPAGE

GWT LOWERING BY TRANSIENT SEEPAGE

GWT lowering SS Seepage

For a given permeability value and Steady-state

- GWT drawdown is nearly proportional to excavation depth.

GWT lowering SS Seepage

Fixed geometry configuration but variation in permeability:

- For SS case, GWT is not dependent on k .
- Pattern of GW heads is function of geometry only and soil layer arrangements

GWT and Transient Seepage

Excavate 5m in 30 days.

Sands, $k=1e-5$ m/s is like SS case

Clays, $k=1e-9$ m/s very little GWT lowered

GWT and Transient Seepage

Excavate next 5m in 30 days.

Sands, $k=1e-5$ m/s is like SS case

Clays, $k=1e-9$ m/s very little GWT lowered

GWT and Transient Seepage

Excavate next 5m in 30 days.

Sands, $k=1e-5$ m/s is like SS case

Clays, $k=1e-9$ m/s very little GWT lowered

GWT in Fully Coupled Flow Models

Excavate 25m, $k=1e-5$ m/s

Lower 8.0m

Excavate 25m, $k=1e-7$ m/s

Lower 4.7m

Excavate 25m, $k=1e-9$ m/s

Lower 2.0m

Excavate 25m in 150 days.

Sands, $k=1e-5$ m/s is like SS case

Clays, $k=1e-9$ m/s very little GWT lowered

CONTENTS

- **Definition drained / undrained**
- **Drained / undrained soil behaviour**
 - Skempton's parameters A and B
- **Modelling undrained behaviour**
 - In terms of effective stresses with drained strength parameters
 - In terms of effective stresses with undrained strength parameters
 - In terms of total stresses
- **Influence of constitutive model and parameters**
 - Influence of dilatancy
 - Undrained behaviour with Mohr-Coulomb Model
 - Undrained behaviour with Hardening Soil Model
- **Consolidation**
- **Example - stability of embankment**
- **Summary**

■ Drained analysis appropriate when

- permeability is high
- rate of loading is low
- short term behaviour is not of interest for problem considered

■ Undrained analysis appropriate when

- permeability is low **and** rate of loading is high
- short term behaviour has to be assessed

■ Implications of undrained soil behaviour

- excess pore pressures are generated

$$\Delta u \neq 0, \Delta \sigma \neq \Delta \sigma'$$

- no volume change

in fact small volumetric strains develop because a finite (but high) bulk modulus of water is introduced in the finite element formulation

- predicted undrained shear strength depends on soil model used
- assumption of dilatancy angle has serious effects on results

PORE PRESSURE PARAMETERS A AND B

Skempton 1954:
$$\Delta p_w = B [\Delta \sigma_3 + A(\Delta \sigma_1 - \Delta \sigma_3)]$$

- fully saturated soil
- no inflow / outflow of pore water
- bulk modulus of soil *grains* >>>
- isotropic linear elastic material behaviour (Hooke's law)

$$\Delta \varepsilon_{\text{vol, skeleton}} = \Delta \varepsilon_{\text{vol, pore water}}$$

$$\Delta \varepsilon_{\text{vol, skeleton}} = \frac{\Delta p'}{K'}$$

$$K' = \frac{E'}{3(1 - 2\nu')}$$

$$\Delta \varepsilon_{\text{vol, pore water}} = \frac{n \Delta p_w}{K_w}$$

PORE PRESSURE PARAMETERS A AND B

Assuming triaxial compression:

$$\Delta\sigma_1; \Delta\sigma_2 = \Delta\sigma_3$$

$$\Delta p_w = \frac{\Delta\sigma_1 + 2\Delta\sigma_3 - 3\Delta p_w}{3K'} \cdot \frac{K_w}{n}$$

leading to

$$\Delta p_w = \frac{1}{1 + \frac{nK'}{K_w}} \left[\Delta\sigma_3 + \frac{1}{3} (\Delta\sigma_1 - \Delta\sigma_3) \right]$$

$$\Delta p_w = B \left[\Delta\sigma_3 + A (\Delta\sigma_1 - \Delta\sigma_3) \right]$$

with

$$B = \frac{1}{1 + \frac{nK'}{K_w}} \quad A = \frac{1}{3}$$

PORE PRESSURE PARAMETERS A AND B

Notes on parameters A and B:

- for K_w large compared to K' , parameter $B \sim 1.0$ (corresponds to $\Delta p_w = \Delta p > \Delta p' = 0$)
- small amount of trapped air reduces parameter B significantly
- parameter A depends on stress path, even for elastic material behaviour
- parameter A cannot be determined a priori for complex elastic-plastic constitutive models > is a result of the model behaviour for the stress path followed

UNDRAINED SHEAR STRENGTH

- Soil behaves as if it was cohesive
- c_u ($= s_u$): undrained shear strength
- c_u only changes if drainage occurs (no change if undrained conditions prevail)

UNDRAINED BEHAVIOUR WITH PLAXIS

UNDRAINED A (analysis in terms of *effective* stresses):
effective strength parameters c' , ϕ' , ψ'
effective stiffness parameters E_{50}' , ν'

UNDRAINED B (analysis in terms of *effective* stresses):
undrained strength parameters $c = c_u$, $\phi = 0$, $\psi = 0$
effective stiffness parameters E_{50}' , ν'

UNDRAINED C (analysis in terms of *total* stresses):
total strength parameters $c = c_u$, $\phi = 0$, $\psi = 0$ **undrained**
stiffness parameters E_u , $\nu_u = 0.495$

UNDRAINED A

Constitutive equations in terms of **effective** stresses: $\Delta\sigma' = D' \Delta\varepsilon$

the **total** stiffness matrix is computed as:

$$D = D' + D_f$$

- single set of parameters in terms of effective stress (undrained, drained, consolidation analysis consistent)
- realistic prediction of pore pressures (if model is appropriate)
- the undrained analysis can be followed by a consolidation analysis (correct pore pressures, correct drained parameters **and c_u is updated automatically**)
- c_u is a consequence of the model, **not an input parameter!!**

Available for all models (including user defined models)!

UNDRAINED C

Constitutive equations in terms of **total** stresses: $\Delta \sigma = D \Delta \varepsilon$

- parameters in terms of total stress
- no prediction of pore pressures (only total stresses are obtained)
- the undrained analysis can not be followed by a consolidation analysis
- c_u is an input parameter!!

Available for Linear elastic, Mohr Coulomb, NGI-ADP models

UNDRAINED B

- parameters in terms of total stress and effective stress
- prediction of pore pressures (but generally unrealistic)
- the undrained analysis should not be followed by a consolidation analysis (pore pressures unrealistic **and c_u is not updated automatically**). Note: "Model change" to effective parameters also not recommended because of unrealistic pore pressure distribution.
- c_u is **an input parameter!!**

Available for Mohr Coulomb, HSM, HSSM, NGI-ADP models

UNDRAINED STRENGTH FROM MOHR-COULOMB

Consider fully undrained isotropic elastic behaviour
(Mohr Coulomb in elastic range)

$\Delta p_w = \Delta p > \Delta p' = 0 \rightarrow$ centre of Mohr Circle remains at the same position

Mohr Circle for evaluating undrained shear strength (plane strain)

Parameters used for Hardening Soil model (HS)

Parameter	Meaning	Value
γ	[kN/m ³] Unit weight (unsaturated)	16
γ_r	[kN/m ³] Unit weight (saturated)	16
φ'	[°] Friction angle (Mohr-Coulomb)	24
c'	[kPa] Cohesion (Mohr-Coulomb)	0
ψ	[°] Angle of dilatancy	0
ν_{ur}	[-] Poisson's ratio unloading-reloading	0.20
E_{ref}^{50}	[kPa] Secant modulus for primary triaxial loading	2 000
E_{ref}^{oed}	[kPa] Tangent modulus for oedometric loading	1 000
E_{ur}^{ref}	[kPa] Secant modulus for un- and reloading	7 500
m	[-] Exponent of the Ohde/Janbu law	1.0
p_{ref}	[kPa] Reference stress for the stiffness parameters	100
$k_{0,nc}$	[-] Coefficient of earth pressure at rest (NC)	$1 - \sin(\varphi')$
R_f	[-] Failure ratio	0.90
$\sigma_{Tension}$	[kPa] Tensile strength	0

Parameters for Soft Soil model and Mohr Coulomb model accordingly

Undrained triaxial test (numerical simulation - **UNDRAINED A**)

Preconsolidation to 100 kPa > compression / extension

Triaxial compression:

$$c_u / \sigma_v' = 0.47 \text{ (MC)}$$

$$c_u / \sigma_v' = 0.35 \text{ (HS)}$$

Triaxial extension:

$$c_u / \sigma_v' = 0.36 \text{ (MC)}$$

$$c_u / \sigma_v' = 0.26 \text{ (HS)}$$

Undrained triaxial test (numerical simulation - **UNDRAINED A**)

Test 1: Preconsolidation to 200 kPa > compression / extension

Test 2: Preconsolidation to 200 kPa > isotropic unloading to 150 kPa > compression / extension

Test 3: Preconsolidation to 200 kPa > isotropic unloading to 100 kPa > compression / extension

Undrained triaxial test (numerical simulation - **UNDRAINED A**)

Test 1: Preconsolidation to 200 kPa > compression / extension

Test 2: Preconsolidation to 200 kPa > isotropic unloading to 150 kPa > compression / extension

Test 3: Preconsolidation to 200 kPa > isotropic unloading to 100 kPa > compression / extension

INFLUENCE OF DIFFERENT FLOW RULE IN HSS MODEL

INFLUENCE INPUT PARAMETERS - HS / HSS MODELS

	E_{50}^{ref}	E_{ur}^{ref}	E_{oed}^{ref}	ϕ'	ψ	c'	$\gamma_{0.7}$	G_0	E_{50}/E_{oed}

COMPARISON UNDRAINED A AND B

Practical example: deep excavation in soft clay

COMPARISON UNDRAINED A AND B

UNDRAINED A:

Mohr-Coulomb effective (ϕ' and c')

UNDRAINED B:

Mohr-Coulomb (c_u)

> significant difference in undrained shear strength

COMPARISON UNDRAINED A AND B

ABH 32

ABH 31

Practical example: deep excavation in soft clay

Method A with **Mohr-Coulomb (!)** overestimates undrained shear strength for normally consolidated soft soils

- > difference in calculated horizontal displacements significant
- > bending moments differ by a factor of 2
- > minor differences in earth

SUMMARY - UNDRAINED BEHAVIOUR

- **FE analysis of undrained conditions should be performed in effective stresses with effective stiffness and strength parameters (Method A)**
- **Method A must be used:**
 - if consolidation/long term analysis is required
 - to exploit all features of advanced soil models
- **Undrained shear strength is a result of the constitutive model**
(check what c_u model predicts; be careful when soil parameters are part of the contract)
- **Dilatancy angle has to be zero**
- **Methods (B) and C provide alternative ways to analyze undrained problems but:**
 - the constitutive model does not generally represent the true soil behaviour (before failure)
 - potentially useful for stability problems in undrained conditions (specification of undrained shear strength is straightforward)

Mesh:

Elements: Interpolation of primary variables

Nodes: Primary variables (displacements, pore pressures)

Stress points: Derived variables (strains, stresses, Darcy velocities)

Same order of interpolation in PLAXIS

PERMEABILITY

- **PLAXIS** allows consideration of change of permeability with void ratio

$$\log \left[\frac{k}{k_0} \right] = \frac{\Delta e}{c_k}$$

Default value for c_k is 10^{15}

- **There may be large contrasts of permeability between different materials in the same problem**
 - Too much permeability contrast may cause numerical difficulties
 - The ratio between the highest and lowest permeability value should not exceed 10^5
 - To simulate an almost impermeable material (e.g. concrete), a value lower by a factor 1000 is usually sufficient

1D CONSOLIDATION - NUMERICAL SIMULATION

drainage at top and bottom

Isochrones at 25% consolidation:
not symmetric for advanced models

1D CONSOLIDATION - NUMERICAL SIMULATION

EXAMPLE - EMBANKMENT CONSTRUCTION

Influence of consolidation on stability
(only possible with **UNDRAINED A and **advanced model**)**

influence of construction speed is investigated

"fast" construction: 2 days of consolidation per placement of 1 m embankment

"slow" construction: 3 days of consolidation per placement of 1 m layer embankment

EXAMPLE - EMBANKMENT CONSTRUCTION

"slow": max. excess porewater pressure: 86 kPa

"fast": max. excess porewater pressure: 100 kPa

EXAMPLE - EMBANKMENT CONSTRUCTION

"slow": stable

"fast": failure

EXAMPLE - EMBANKMENT CONSTRUCTION

SIMPLIFIED REPRESENTATION OF STRESS PATH

$$t = \frac{1}{2} (\sigma_1 - \sigma_3)$$

- **Conclusion**

Soft Soil and Soft Soil in Indonesia

- Soft soil deposits (soft clays, organic soils, and peats) are normally characterized by **low shear strength, high compressibility and low coefficient of permeability**. Characteristics which make them a difficult soil for engineering .
- Soft Soil deposits can be found throughout world and are also prevailing in many parts of Indonesia.
- Indonesia possesses one of the **longest coastal-line** in the world with many of them having soft soil deposits.
- The area of soft soil deposits in Indonesia is around **30%** of Indonesia's total land area (**60 million-ha with 20 million-ha is peats**) with varying depth (black area and some white area on the map).

Ground Improvement and Vertical Drains

- **Ground improvement** techniques play an important role in extending the infrastructure across the country in difficult soils.
- **Preloading and vertical drains**, vibro compaction and replacement, in situ soil mixing, grouting, dynamic compaction, piles, geosynthetics, electro-osmotic, etc, are some ground improvement techniques.
- The selection of the correct ground improvement technique can have an important effect on the foundation choice and can often lead to more **economical solutions** when compared to traditional approaches.

- **Vertical drains combined with preloading** have become common practice and are among the most effective procedures for ground improvement **accelerating the consolidation process** (decrease the time for reaching final settlements).
- The installation of vertical drains **reduces the drainage path** and speeds up the dissipation of excess pore water pressure generated during the application of surcharge loads in saturated fine grained soils.

Vertical Drains

- The installation of vertical drains provides a **shorter drainage path** and a faster dissipation of excess pore water, thereby resulting in **faster development of settlements** and a quicker gain of strength due to consolidation.

Prefabricated Vertical Drains (PVD)

- Prefabricated vertical drains (PVD) are typically **10 cm wide, 3 to 9 mm thick**, and packed in rolls.
- The drain consists of a **geotextile filter** wrapped on a **plastic strip** with **molded channels** that allow water to travel to the ground surface, relieving excess subsurface pore water pressure.
- The geotextile filter prevents soil particles from entering the channels and **clogging** the drain.

Installation of Prefabricated Vertical Drains (PVD)

- The installation equipment consists of the **drain spools, mandrel, anchor and PVD delivery route** excavator or crane.
- The mandrel cross-sectional area is typically **60 - 80 square cm**.
- The installation force is typically provided by **vibratory methods, static methods** or a combination of these methods depending on the soil conditions.
- The majority of depths for PVD applications are between **5 - 40 m**, however, drains can be installed **up to 60 m**.

Installation of Prefabricated Vertical Drains (PVD)

- The wick drain is threaded through the **mandrel** which protects it from damage as it is driven through the soil.
- After reaching the target depth, the drain is **anchored** to keep it in place while the mandrel is withdrawn.
- The drain is then cut approximately **10 to 30 cm** above ground, and a new anchor fastened to the wick at the bottom of the mandrel in preparation for the next installation point.
- The drains layout usually consists of **triangular or square grid patterns** and center-to-center spacing is usually in the range of **0.5 - 2.5 m**.

Single Drained

Double Drained

Assumptions made in analytical solution :

- **Single cylindrical** drainage cell model (each drain is independent at the centre of a cylindrical soil mass, i.e. valid only below centreline of embankments neglecting lateral deformations).
- **Homogeneous** soil layer or limited number of soil layer (one or two soil layer problems).
- Load distribution is **uniform**.
- **Instantaneously** applied load or limited steps and rate of loading.
- Based on **simple** soil models.

Horizontal Consolidation – Barron (1948)

$$\bar{U}_h = 1 - e^{\left(\frac{-8T_h}{\nu}\right)} \quad T_h = \frac{c_h \cdot t}{D^2} \quad c_h = \frac{k_h \cdot E_{oed}}{\gamma_w}$$

$$\nu = \frac{n^2}{n^2 - 1} \cdot \ln(n) - \frac{3}{4} + \frac{1}{4n^2} \quad \dots (\text{drain spacing factor})$$

$$\nu = \frac{n^2}{n^2 - s^2} \cdot \ln\left(\frac{n}{s}\right) - \frac{3}{4} + \frac{s^2}{4n^2} + \frac{k_h}{k_s} \cdot \frac{n^2 - s^2}{n^2} \cdot \ln(s) \quad \dots (\text{drain spacing and soil disturbance factor})$$

$$n = \frac{D_e}{d_w} \quad s = \frac{d_s}{d_w}$$

Where,

U_h = average degree of consolidation on a horizontal plane,

u = parameter for perfect drain condition and with smear condition,

T_h = time factor for radial drainage,

c_h = coefficient of consolidation for radial drainage,

k_h = undisturbed horizontal permeability,

k_s = horizontal permeability in the smear zone,

d_e = equivalent influence zone diameter,

d_w = equivalent drain diameter,

d_s = equivalent smear zone diameter.

Vertical Consolidation – Terzaghi (1925)

$$U_z = 1 - \sum_{m=0}^{m=\infty} \left(\frac{2}{M} \sin(MZ) e^{(-M^2 T_v)} \right)$$

$$M = \frac{2m+1}{2}\pi \quad Z = \frac{z}{H}$$

$$T_v = \frac{c_v \cdot t}{H^2} \quad c_v = \frac{k_v \cdot E_{oed}}{\gamma_w}$$

Where:

U_z = vertical degree of consolidation,

T_v = vertical time factor,

c_v = vertical coefficient of consolidation,

k_v = undisturbed vertical permeability,

H = height of drainage path ($H/2$ for double drainage and H for single drainage).

Combination of Vertical and Horizontal Consolidation – Carillo (1942)

$$\bar{U} = 1 - (1 - \bar{U}_v)(1 - \bar{U}_h)$$

Where,

U = combination of vertical and horizontal degree of consolidation

U_v = vertical degree of consolidation,

U_h = horizontal degree of consolidation.

PVD with Vacuum Preloading

- Kjellman first introduced a vacuum preloading to accelerate consolidation in 1952 and a small field test was performed.
- In this method the soil load is replaced by **atmospheric pressure**

PVD with Vacuum Preloading

Vacuum without Membrane

Vacuum vs Non Vacuum

Type	Total stress	Initial /boundary condition	Process	Effect
Vertical drain with surcharge	$\sigma \uparrow (\Delta\sigma)$	$u \uparrow (\Delta u)$ σ'	$\Delta u \rightarrow \sigma'$	$\sigma' \uparrow$ $(\Delta u \approx \Delta\sigma)$

$$\sigma = u + \sigma'$$

Vacuum vs Non Vacuum

Type	Total stress	Initial /boundary condition	Process	Effect
Vacuum	σ	$u(soil)$ $-u^*(boundary)$ σ'	$u \downarrow$ $(\Delta u \approx -u^*)$	$\sigma' \uparrow$ $(\Delta u \approx -u^*)$

$$\sigma = u + \sigma'$$

Vacuum vs Non Vacuum

PVD with Conventional Soil Prelading

1. Higher Surcharge
2. Lower Stability
3. Greater Lateral Movement
4. Many heavy equipment
5. Longer Construction Time

PVD with Vacuum Preloading

1. Lower or no Surcharge
2. Better Control of Stability
3. Less Lateral Movement
4. Less heavy equipment
5. Shorter Construction Time

Vacuum vs Non Vacuum

Vertical Displacement – Comparison PVD with Conventional Soil Preloading (four meters surcharge) vs PVD with Conventional Soil Preloading + Vacuum Preloading (four meters surcharge + 80 KPa Vacuum Pressure)

Conclusion

- **Analytical methods** for evaluating the effect of vertical drains usually assume consolidation within a **uniform soil column** with linear compressibility characteristics without any lateral movement.
- **Numerical methods** provide a less restrictive analysis compared to analytical methods, such as: **advanced soil models**, **multiple drain** analysis, **multi layer** subsoil condition, **staged construction**, **non uniform load** distribution (lateral displacement and stability analysis), variation of **drains configuration** (spacing and floating), effects of a sand mat and reinforcement with geosynthetic, etc.
- The **equivalent 2D plane strain** approach is sufficient to conduct **multi-drain analysis** in large projects, where the application of a 2D plane strain model is efficient both from a computational time point of view and with respect to the accuracy of the predictions (compared with a full 3D model and 2D Axisymmetric model).

Conclusion

- For floating PVDs, the drain length can be reduced to 70% (double drained) and 80% (single drained) of the entire soft clay thickness without significantly affecting the consolidation process.
- The Advantages Vacuum Consolidation Method compare with conventional soil preloading are Lower or no surcharge, better control of stability, less lateral movement, less heavy equipment, shorter construction time.

...Thank You...

CG13

**EXERCISE 4: Modelling of Embankment
Improved with Vertical Drains**

Ikhya Ikhya

COMPUTATIONAL GEOTECHNICS

INTRODUCTION

The exercise concerns in the **consolidation analysis with vertical drains (with and without drains, with and without smear effect, with and without vacuum)**. In order to keep the problem as simple as possible, only one soil layer is considered.

Objectives:

- Consolidation analysis
- Modelling drains
- Change of horizontal permeability (k_x)
- Updated mesh analysis (large deformations)
- Introduction Vacuum Consolidation

Figure 1: Scheme of the exercise

INPUT

Figure 1 shows a cross section of a **road embankment**. The embankment is **20.0 m wide** and **4.0 m high**. The slopes have an inclination of **1:1.5**. The problem is symmetric, so **only one half is modelled** (in this case the right half is chosen). The embankment itself is composed of **sandy soil**. The subsoil consists of **12.0 m of soft soil**. The phreatic level is located **0 m** (at the original ground surface). Under the soft soil layer there is a **Impermeable Soil Layer**.

General settings

- Start the Input program and select Start a new project from the Quick select dialog box.
- In the Project tabsheet of the Project properties window, enter an appropriate title (*PVD Consolidation*).
- In the Model tabsheet make sure that Model is set to **Plane strain** and that Elements is set to **15-Noded**.
- Define the limits for the soil contour as $x_{min} = 0.0$, $x_{max} = 64.0$, $y_{min} = -12.0$ and $y_{max} = 4.0$.

Figure 2: Project tabsheet and Model tabsheet of the Project properties window

Definition of soil stratigraphy

The sub-soil layer are defined using a **borehole**. The embankment layers are defined in the **Structures mode (soil polygon)**.

To define the soil stratigraphy:

- Create a borehole at $x = 0$. The Modify soil layers window pops up.
- Define single soil layer as shown in Figure 3.
- The water level is located at $y = 0$ m. In the borehole column specify a value of 0 to Head.

Figure 3: Modify soil layer window.

- Open the Material sets window.
- Create soil material data set according to Table 1 and assign them to the corresponding layer in the borehole (Figure 3).

- Close the **Modify soil layers window** and proceed to the **Structures mode to define the embankment and drains**.

Table 1: Material properties

Figure 4: General tabsheet of the soil and interface data set window

Figure 5: Material sets window.

Definition of Embankment and Drains

The embankment and the drains are defined in the **Structures mode**.

To define the embankment layers:

- Click the **Create soil polygon** button in the **side toolbar** and select the **Create soil**

polygon option in the appearing menu.

- **Define the embankment** in the **draw area** by clicking on (0.0 0.0), (0.0 4.0), (10.0 4.0) and (16.0 0.0).
- **Right-click** the created polygon and **assign the Embankment data set to the soil polygon** (Figure 6).
- **To define the embankment construction level** click the **Cut polygon** in the **side toolbar** and **define a cutting line** by clicking on (0.0 2.0) and (13.0 2.0). The embankment cluster is split into two sub-clusters.

Figure 6: Assignment of a material dataset to a soil cluster in the draw area.

In this project the effect of the drains on the consolidation time will be investigated by comparing the results with a case without drains.

- **Click the Create hydraulic conditions button** in the **side toolbar** and **select the Create drain option** in the appearing menu (Figure 7).

Figure 7: The Create drain option in the Create hydraulic conditions menu

- **Drains are defined in the soft layer ($y = 0.0$ to $y = -12.0$).** The distance between two consecutive drains is 2 m. Considering the symmetry, the first drain is located at 1 m distance from the model boundary.
- **8 drains** will be created in total (Figure 8)

Figure 8: Final geometry of the model

MESH GENERATION

- Proceed to the **Mesh mode**
- Generate the mesh. Use the default option for the **Element distribution parameter (Medium)**. (Figure 9). 
- **View the generated mesh.** The resulting mesh is shown in Figure 10. 
- Click on the **Close** tab to close the **Output program**.

Figure 9: Mesh options window.

Figure 10: The generated mesh in the Output window.

CALCULATIONS

Once the mesh has been generated, the finite element model is complete. **The calculation phases** to simulate the stages of construction are shown in **Table 2**.

Table 2. Calculation phases

No	Staged Construction	Days
1	Initial condition	-
2	Install PVD	2
3	2.0 Embankment (+2.0m)	2
4	Consolidation	1
5	2.0 Embankment (+4.0m)	2
6	Consolidation	10
7	Final Consolidation	-

Initial Phase: Initial Conditions

In the **initial situation** the **embankment is not present**. In order to generate the initial stresses therefore, **the embankment must be deactivated first in the Staged construction mode**.

In the **Staged construction mode** deactivate the two clusters that represent the **embankment**, just like in a staged construction calculation. When the embankment has been deactivated (the corresponding clusters should have the background colour), the remaining **active geometry is horizontal with horizontal layers**, so the **K0 procedure can be used to calculate the initial stresses** (Figure 11).

- In the **Model explorer** expand the **Soils subtree**.
- Expand the **Soils subtree** and **deactivated** The Embankment.

The **initial water pressures are fully hydrostatic and based on a general phreatic level located at $y = 0$** . Note that a **phreatic level is automatically created at $y = 0$** , according to the value specified for **Head in the borehole**.

Figure 11: Configuration of the initial phase.

In addition to the phreatic level, attention must be paid to the **boundary conditions for the consolidation analysis** that will be performed during the calculation process. **Without giving any additional input, all boundaries except for the bottom boundary are draining so that water can freely flow out**

of these boundaries and excess pore pressures can dissipate. In the current situation, however, **the left vertical boundary must be closed because this is a line of symmetry, so horizontal flow should not occur. The bottom horizontal boundary also closed because the excess pore pressures cannot be dissipated through Impermeable Soil Layer.** The remaining boundaries are open because the excess pore pressures can be dissipated through these boundaries. In order to define the appropriate consolidation boundary conditions, follow these steps:

- In the **Model explorer** expand the **Model conditions subtree**.
- Expand the **GroundwaterFlow subtree** and set Boundary **XMin and YMin to Closed** (Figure 12).

Figure 12: The boundary conditions of the problem.

Consolidation Analysis

A consolidation analysis introduces the dimension of time in the calculations. In order to correctly perform a consolidation analysis a proper time step must be selected. The use of time steps that are smaller than a critical minimum value can result in stress oscillations.

The consolidation option in PLAXIS allows for a fully automatic time stepping procedure that takes this critical time step into account. Within this procedure there are three main possibilities:

- Consolidate for a predefined period, including the effects of changes to the active geometry (**Staged construction**).
- Consolidate until all excess pore pressures in the geometry have reduced to a

predefined minimum value (**Minimum excess pore pressure**).

- Consolidate until a specified degree of saturation is reached (**Degree of consolidation**).

The **first two possibilities will be used in this exercise**. To define the calculation phases, follow these steps:

Phase 1: Install PVD

The first calculation stage is a **Consolidation analysis, Staged construction**.

- **Add a new phase.** 
- In the Phases window select the **Consolidation** option from the **Calculation type** drop-down menu in the General subtree.
- Make sure that the **Staged construction** option is selected for the **Loading type**. 
- Enter a **Time interval** of **2 days**. The default values of the remaining parameters will be used.
- In the **Model explorer** expand the **Drains** subtree and **activated The PVD** (figure 13).
- **Click the Material sets windows button in the side toolbar. Copy clay material (clay ps) and select the flow parameters to change horizontal soil permeability (kx) with equivalent horizontal permeability for plane strain condition (khp) (table 4). Change (clay layer) with (clay ps).** 

Figure 13: Phase 1.

Table 3: PVD parameters

No	PVD parameters	Formula	Units
1	Space of triangular grid pattern(s)		1.9 m
2	Installation depth (l)		-12m
3	Mandrel diameter (dm)		88 mm
4	Efektif space(de)	$1.05 \times s$	2 m
5	Equivalence PVD diameter (dw)	$2(a + b)$	52mm
6	Smear are diameter (ds)	$\frac{5}{2} d_n$	220mm
7	The permeability in the smeared zone(Ks)	$K_h/k_s = 2$	2.15×10^{-4} m/day

Table 4: Equivalent Horizontal Permeability

Equivalent Horizontal Permeability (Hird et al. 1992)			
Horizontal Permeability	Formula	Units	Description
K_h (kx)		4.32×10^{-4} m/day	Horizontal permeability undisturb soil
k_{hp}	$\frac{k_{hp}}{k_h} = \frac{0,67}{[\ln(n) - 0,75]}$	9.98×10^{-5} m/day	equivalent horizontal permeability without smear zone
k_{hp}'	$\frac{k_{hp}'}{k_h} = \frac{2}{3 \left[\ln \left(\frac{R}{r_c} \right) + \left(\frac{k_h}{k_c} \right) \ln(s) - \frac{3}{4} \right]}$	6.63×10^{-5} m/day	equivalent horizontal permeability with smear zone

Figure 14: Phase 1.

Phase 2: Embankment 1

The second calculation stage is also a **Consolidation analysis, Staged construction**.

- **Add a new phase.** 
- In the Phases window select the **Consolidation** option from the **Calculation type** drop-down menu in the General subtree.
- Make sure that the **Staged construction** option is selected for the **Loading type**. 
- Enter a **Time interval** of **2 days**. The default values of the remaining parameters will be used.
- In the **Model explorer** expand the **Soils subtree** and **activate the first part of the Embankment** (figure 14).

- Change **max steps** from **250 (default)** to **1000** by click Edit Phase

Figure 15: Phase 2.

Phase 3: Consolidation 1

The third phase is also a **Consolidation analysis, Staged construction**. In **this phase no changes to the geometry** are made as **only a consolidation analysis to ultimate time is required**.

- **Add a new phase.** 
- In the Phases window select the **Consolidation option** from the **Calculation type** drop-down menu in the General subtree.
- Make sure that the **Staged construction** option is selected for the **Loading type**. 
- Enter a **Time interval** of **1 day**. The default values of the remaining parameters will be used.

Phase 4: Embankment 2

The fourth calculation stage is once again a **Consolidation analysis, Staged construction**.

- **Add a new phase.** 
- In the Phases window select the **Consolidation option** from the **Calculation type** drop-down menu in the General subtree.
- Make sure that the **Staged construction** option is selected for the **Loading type**. 
- Enter a **Time interval** of **2 days**. The default values of the remaining parameters will be used.
- In the **Model explorer** expand the **Soils subtree** and **activate the second part of the Embankment** (figure 15).
- Change **max steps** from **250 (default)** to **1000** by select Edit Phase

Figure 16: Phase 4.

Phase 5: Consolidation 2

The fifth phase is also a **Consolidation analysis, Staged construction**. In this phase **no changes to the geometry** are made as only a consolidation analysis to **ultimate time** is required.

- **Add a new phase.** 
- In the Phases window select the **Consolidation** option from the **Calculation type** drop-down menu in the General subtree.
- Make sure that the **Staged construction** option is selected for the **Loading type**. 
- Enter a Time interval of **10 day**. The default values of the remaining parameters will be used.

Phase 6: Final Consolidation

The sixth phase is a **Consolidation analysis to a minimum excess pore pressure**.

- **Add a new phase.** 
- In the Phases window select the **Consolidation** option from the **Calculation type** drop-down menu in the General subtree.
- Select the **Minimum excess pore pressure option** in the **Loading input** drop-down menu and accept the default value of 1 kN/m² for the minimum pressure. The default values of the remaining parameters will be used.

Execution of calculation:

Before starting the calculation, click the **Select points for curves** button and select the following points (figure 16):

Point A (0 0) will be used to plot the development of vertical displacement.

Point B (0 -6) will be used to plot the development (and decay) of excess pore pressures.

Figure 17: Point A and B.

After selecting these points, start the calculation

During a consolidation analysis the development of time can be viewed in the upper part of the calculation info window.

In addition to the multipliers, a parameter $P_{\text{excess,max}}$ occurs, which indicates the current maximum excess pore pressure. This parameter is of interest in the case of a Minimum excess pore pressure consolidation analysis, where all pore pressures are specified to reduce below a predefined value.

Figure 18: Calculation progress displayed in the Active task window.

RESULTS

After the calculation has finished, select the '**View calculation**' button that will start the output program.

Check the various types of output, such as the **deformed mesh**, **displacement contours**, **excess pore pressure (P_{excess})**, etc. These can be found from the '**Deformations**' and '**Stresses**' menus.

Figure 19: Vertical Displacement (u_y)

Figure 20: excess pore pressure (P_{excess}) with PVD

The Curves manager can be used to view the development, with time, of the excess pore pressure under the embankment (Point B) (figure 20).

In order to create such a curve, follow these steps:

- For the x-axis, select the Project option from the drop-down menu and **select Time** in the tree.
- For the y-axis select the point in the middle of the soft soil layers (**Point B**) from the drop-down menu. In the tree select **Stresses** → **Pore pressure** → **pexcess**.

Figure 21: Development of excess pore pressure under the embankment (Point B)

Also

the Curves manager can be used to view the development, with time, of the vertical displacement (U_y) of the embankment (Point A and B).

In order to create such a curve, follow these steps:

- **For the x-axis**, select the Project option from the drop-down menu and select **Time** in the tree.
- **For the y-axis select the point** in the top of the soft soil layers (Point A) and also can be select the point in the middle of the soft soil layers (Point B) from the drop-down menu. In the tree select **Deformation** → **Total Displacements** → **u_y** .

Figure 22: Displacement versus time for the point A

Figure 23: Displacement versus time for the point A and B

WITHOUT PVD VS ONLY PVD VS PVD WITH SMEAR

Consolidation analysis PVD with Smear zone

- **Save as** this work.
- Click the **Material** sets windows button in the side toolbar and **select “clay ps” material to change the flow parameters** from equivalent horizontal permeability for plane strain condition (without smear) (**khp**) with equivalent horizontal permeability for plane strain condition (with smear) (**khp'**) (table 4)

Consolidation analysis without PVD

- **Save as** this work.
- In the **Model explorer** expand the Model conditions subtree, expand the **Drains subtree** and **deactivated The PVD**.
- Click the **Material** sets windows button in the side toolbar and **select “clay ps” material to change the flow parameters** from equivalent horizontal permeability for plane strain condition (without smear) (**khp**) with original horizontal soil permeability (**kx**).

Figure 24: excess pore pressure (P_{excess}) Without PVD

Comparison curve using the PVD only, PVD + smear effect, and without PVD

Figure 26: Displacement versus time (Point A)

Comparison curve using the PVD only, PVD + smear effect, and without PVD

Modelling Vacuum Consolidation

There are various methods of vacuum consolidation in the real world, but they are all modelled in similar way in Plaxis. Most methods in reality are using vertical drains, which are somehow connected at the top to an air pump that reduces the air pressure in the drains until near-vacuum exist. In Practice, a complete vacuum (100 kN/m² pressure) is not achievable, but an effective under-pressure of 60-90 kN/m².

Since Plaxis does not take air pressure into account (atmospheric pressure is assume to be the zero reference pressure level), a reduction of the groundwater head is used instead to simulate vacuum consolidation). It is modelled leads to negative pore stresses (suction), which are not there in reality.

Vacuum Consolidation analysis

Open File Analysis Consolidation with PVD (without smear).

- **Save as** this work.
- Click the **Material** sets windows button in the side toolbar and select the material data set. Arrange the parameters in material data set, so the saturated condition apply to this volume. 
 - o Change unsaturated unit weight (γ_{unsat}) in clay soil parameter (General tabsheet of the material data set), must be set equal to the saturated unit weight, γ_{sat}

Figure 273: Material set for clay parameter $\gamma_{\text{unsat}} = \gamma_{\text{sat}}$

- o In Groundwater tabsheet for clay parameter, hydraulic model must be set to *saturated* after selecting Data Set : *User-defined*

(a)

(b)

Figure 284: Groundwater model for Vacuum Consolidation :

(a) Data Set : User Defined, (b) Model : Saturated

- In **Phase Explorer** for stages construction,
 - o Click 'initial phase' and de-select the **ignore suction** option in Deformation control parameters sub tree. Do exactly same for all phases.

Figure 295: De-select Ignore suction

- o from Initial Phase to 'Consol 2 (Phase 5)'. Change Phreatic to **Steady state groundwater flow** In pore pressure calculation (general tab)

Figure 306: Steady state groundwater flow for pore pressure calculation

- o In 'Embankment 1 (Phase 2)', **Select all drains**. Expand *selection explorer* and *sub tree* of drain. Then **change behaviour of drain from normal to vacuum**. Input head (h) must be underpressure (**-8 m**). Do exactly same

Figure 317: Modelling vacuum behavior

Figure 28: Displacement versus time (Point A)

Comparison curve using the Vacuum Consolidation and without Vacuum Consolidation

Figure 29: Excess pore pressure versus time (Point B)

 - examples
 - final advice
- **Comparison Phi-c-reduction – Limit equilibrium analysis**
- **Comparison Phi-c-reduction – Limit analysis**
- **Non-associated plasticity**

- **Initial stresses represent the equilibrium state of stress of the undisturbed soil and consist of:**
 - Soil weight
 - Loading history

- **In Plaxis two possibilities exist:**
 - K0-procedure
 - Gravity loading

GENERATION OF INITIAL STRESSES AS FIRST STEP IN CALCULATION K_0 -PROCEDURE

- **Needed:**
coefficient for lateral earth pressure K_0
- **Disadvantage:**
No equilibrium for inclined surface (a nil-step can be used)
- **Advantage:**
No displacements are generated, only stresses, can take into account initial OCR or POP

CASES WHERE GRAVITY LOADING SHOULD BE USED INSTEAD OF K_0 -PROCEDURE

SPECIAL CASES

For example a slope in overconsolidated soil or if (approximate) modelling of geological history is required

Gravity loading needed due to geometry, but initial OCR or POP required

SPECIAL CASES

For complex initial situations like inner city building projects it may be needed to use several calculation phases to model the current situation before starting the calculation for the actual project.

Methods of assessing the factor of stability problems:

- Limit equilibrium method > generally used in practical engineering
- Displacement finite element method > phi-c-reduction (strength reduction method)
- Finite element limit analysis

Limit equilibrium analysis

- Overall form of the failure surface needs to be determined in advance
- Distribution of the interslice forces is assumed differently in various methods
- Kinematic admissibility is not ensured
- Need to perform a global search for identifying the failure mechanism with the lowest factor of safety

DISPLACEMENT FINITE ELEMENT METHOD > PHI-C-REDUCTION

Factor of safety: Many possible definitions

$$\frac{\text{available soil resistance}}{\text{mobilized soil resistance}} = 1.8$$

$$\frac{\text{failure load}}{\text{working load}} = 5.9$$

PLAXIS: Safety factor on soil resistance

- Strength reduction method: Phi-c-reduction (safety analysis)
- Same numerical tool as for serviceability design
- Automatically detects most critical failure mechanism

- Reduction of strength parameters c and $\tan(\varphi)$ until failure is reached.
- The factor of safety is then defined as:

$$\Sigma Msf = \frac{c}{c_{reduced}} = \frac{\tan \varphi}{\tan \varphi_{reduced}}$$

Calculation procedure:

- Create a Safety Phase
- Accept the default increment for $M_{sf} = 0.1$ from the multiplier tab-sheet
- Calculate
- Carefully examine ΣM_{sf} vs. displacement curve in Plaxis Curves to assure that failure is indeed reached
- If so, the value of ΣM_{sf} is assumed to be the factor of safety on soil resistance

Notes:

- In order to check failure, select a control point within the (expected) failing body
- Use sufficient number of load steps
- Choose elasto-plastic behaviour for wall, anchors and geotextiles with realistic full plastic values in order to prevent excessively high structural forces
- **Displacements etc. AFTER safety analysis are meaningless**

MAIN ADVANTAGES OF PHI-C-REDUCTION METHOD

- Requires no **a-priori assumptions** on the failure mechanism
- Critical surface is **found automatically** as slope failure occurs naturally through the zones due to insufficient shear strength to resist shear stresses.
- No requirement of assumptions on e.g. inter-slice shear force distribution
- Applicable to complex conditions
- Numerical tool same as for deformation analysis
- Powerful alternative approach

INFLUENCE OF MESH DISCRETIZATION

15-noded elements	Factor of Safety
5	1.90
11	1.62
(very coarse) 38	1.52
(coarse) 82	1.51
(medium) 170	1.50
(fine) 414	1.45
(very fine) 871	1.43

EXAMPLE - SOIL NAILING

EXAMPLE - SOIL NAILING

Nails **elastic**: safety factor from ϕ/c - reduction: 1.18

EXAMPLE - SOIL NAILING

Nails **plastic**: safety factor from ϕ/c - reduction: 1.07

EXAMPLE - SOIL NAILING

nails elastic: max. force 181 kN/m

nails plastic: max. force 75 / 40 kN/m as specified

SOME FINAL ADVICE FOR PHI-C-REDUCTION

- Always inspect the incremental displacements or strains as computed in the last load step to make sure that failure is reached.
- The mesh used in the calculation needs to be sufficiently fine.
- Mesh: Refine and redo the phi-c analysis until the factor of safety remains constant upon further refinement of the mesh.
- Always use the arc-length time stepping procedure within the phi-c-reduction (default)
- Use a small tolerated error (maximum should be the default error of 1%)
- Beware of three-dimensional effects
- Check for local, not relevant, failure mechanisms

SUMMARY

- **Strength reduction techniques (phi-c-reduction) are well suited to calculate factors of safety for slopes**
- **It can be shown that results compare extremely well with rigorous limit analyses**
- **For high values of friction angles and low values of dilatancy angles numerical instabilities may occur**
- **Numerical instabilities of non-associated displacement finite element analyses can be avoided by employing a modified Davis approach.**
- **The modified Davis procedure can be used with displacement based finite element analysis and finite element limit analysis**

PARTIAL SATURATION OF SOILS

PARTIAL SATURATION OF SOILS

Regions in a soil segment:

- suction:
 - unsaturated zone (unsaturated)
 - capillary fringe (quasi-saturated – suction)
- pore water pressure:
 - zone with entrapped air (quasi-saturated – pore water pressure)
 - saturated zone (saturated)
- for fluctuating water tables above ground surface zone with entrapped air is relevant

PARTIAL SATURATION OF SOILS

$$n = \frac{V_{pores}}{V_{total}} = \frac{V_{liquid} + V_{gas}}{V_{total}}$$

Porosity

$$S_r = \frac{V_{liquid}}{V_{pores}} = \frac{V_{liquid}}{V_{liquid} + V_{gas}} = 1 - S_g$$

Degree of saturation

SOIL WATER CHARACTERISTIC CURVE (SWCC) / RETENTION CURVE

RETENTION CURVES

- Retention curves exhibit hysteresis effects
- This value of negative water pressure is called the air entry value (small for sands, large for clays) for that soil (suction is not strong enough to draw out water from the soil)
- Negative pore pressures can exist in saturated soils

RETENTION CURVES - EXAMPLES

(Brooks and Corey, 1964)

HYDRAULIC PARAMETERS: DATA SET

- **Standard** (Topsoil part of Hypres)
- **Hypres** (International soil classification system)
- **USDA** (International soil classification system)
- **Staring** (Dutch soil classification system)
- **User-defined**

- Parameter values are provided depending on soil classification
- Hydraulic parameters must be chosen very carefully!

PERMEABILITY

Unsaturated soils: Darcy's law

$$q = -k \frac{\partial h}{\partial y} = -k \frac{\partial \phi}{\partial y}$$

$$h = \phi = y + \frac{p_w}{\gamma_w}$$

$$k = k_{rel}(S_r) k_{sat}$$

Permeability decreases in partially saturated soils

Fredlund & Rahardjo (1993)

PERMEABILITY

$$k_{rel}(S_r) = (S_e)^{g_l} \left(1 - \left(1 - S_e^{\left(\frac{g_n}{g_n - 1} \right)} \right)^{\left(\frac{g_n - 1}{g_n} \right)} \right)^2 \quad S_e = \frac{S_r - S_{residu}}{S_{sat} - S_{residu}}$$

VOLUMETRIC BEHAVIOUR

Suction increases the apparent preconsolidation stress and (often) soil stiffness

(Oedometer tests on a Brazilian residual soil; Lemos, 1998)

VOLUMETRIC BEHAVIOUR

Volume change behaviour
on saturation depends on
applied stress level

VOLUMETRIC BEHAVIOUR

Isotropic plane

VOLUMETRIC BEHAVIOUR - SUMMARY

Features of volumetric behaviour:

- suction increases the apparent preconsolidation pressure (yield stress) and (often) soil stiffness
- volumetric behaviour depends on stress level. Swelling or compression (“collapse”) may occur depending on applied load
- collapse behaviour
 - after collapse soil lies on saturated consolidation line
 - volume change reversal may occur during collapse
 - in loose soils, collapse strains reach a maximum at a certain intermediate stress level
- volume change behaviour is path independent only for a certain class of stress paths
- suction changes may lead to irreversible deformations

SOIL STRENGTH

$$\tau_f = c' + (\sigma_n - p_a) \tan \phi' + s \tan \phi^b$$

Shear strength increases with suction

Fredlund & Rahardjo (1985)

Shortcoming: close to saturation ϕ^b should be equal to ϕ' but this gives jump and too high strength with very low saturation

SOIL STRENGTH

Effective stresses in partially saturated soils (Bishop 1959) – other definitions possible

$$\sigma' = (\sigma - u_a) + \chi (u_a - u_w)$$

- σ' and σ = effective and total stresses
- u_a = pore air pressure
- u_w = pore water pressure
- $(u_a - u_w)$ = capillary tension
- χ = Bishop parameter
varies from 0 (dry) to 1 (fully saturated)

Assuming that, $u_a \approx 0$ and $\chi \approx S$ the equation simplifies to:

$$\sigma' = (\sigma - S u_w)$$

COEFFICIENT χ

SOIL STRENGTH

$$\sigma' = (\sigma - S_r u_w)$$

Check this product!

$$\tau_f = c' + \sigma'_n \tan \varphi' = c' + (\sigma_n - S_r u_w) \tan \varphi' = c' + \sigma_n \tan \varphi' - S_r u_w \tan \varphi'$$

The variation of shear strength with suction depends on the variation of S_r with suction

- Often S_r is replaced by S_e (PLAXIS!)

$$S_e = \frac{S_r - S_{res}}{S_{sat} - S_{res}}$$

S_e : effective saturation

S_r : degree of saturation

S_{res} : residual saturation (suction $\rightarrow \infty$)

S_{sat} : saturation when (suction=0)

SOIL STRENGTH

Sand (USDA): ($S_{res}=10,5\%$)

DEFINITION OF QUASI-SATURATED

„Where air is entrapped in soils beneath the groundwater table, the soils are not fully saturated.....we would like to introduce a new term, „**quasi-saturated soils**“, that will be used to define soils beneath the water table which contain entrapped air.“

(Faybishenko, B.)

DEFINITION

Stages of saturation:

- closer look to area near saturation
- distinction of quasi-saturated stage between zone with positive and negative pore water pressure

Reference: Boutonnier, 2013

DEFINITION

Regions in a soil segment:

- suction:
 - unsaturated zone
(unsaturated)
 - capillary fringe
(quasi-saturated – suction)
- pore water pressure:
 - zone with entrapped air
(quasi-saturated – pore water pressure)
 - saturated zone
(saturated)
- for fluctuating water tables above ground surface
zone with entrapped air is relevant

- Unsaturated soil slope subjected to rainfall infiltration
- Summary and conclusions

Definition of safety factor obtained by FEM (available = characteristic value)

$$\eta_{fe} = \frac{\tan\varphi_{\text{available}}}{\tan\varphi_{\text{failure}}} = \frac{c_{\text{available}}}{c_{\text{failure}}}$$

Basically 2 possibilities to obtain factor of safety:

1: Calculation with **characteristic** parameters > automatic reduction of strength parameters of soil until equilibrium is no longer achieved in numerical analysis

Some FE-codes do this automatically > strength-reduction technique

2: Calculation with **reduced** parameters > perform *new* calculation with different factors until equilibrium is no longer achieved in numerical analysis

Some codes do this automatically

Fine Mesh (3233 elements):

No difference in results for Method 1 and 2

Incremental shear strains after ϕ/c -reduction

Advantage of FEM vs. LEM for Slope Stability Analysis

1. In the **FEM**, failure occurs naturally through the zones within the soil mass wherein the shear strength of the soil is not capable to resist the applied shear stress, so there is **no need to make assumption about the shape or location of the failure surface**.
2. There is no theory of slices in the **FEM**, so **no need to make assumption about slide side forces**. The FEM maintains overall equilibrium until failure is reached.
3. As long as the compressibility data of soils is available, the **FEM** will **provide deformations** result at the working stress levels.
4. The **FEM** is capable to check **the progressive failure** up to and including shear failure.

Unsaturated soil slope subjected to rainfall infiltration

In slope stability analysis, the effect of negative pore water pressure or suction is usually not taken into account because suction will reduce with rainfall infiltration and therefore it can be assumed that matric suction does not influence the long term stability of the slope.

However, to reduce matric suction from the soil, the rainfall needs to be sustained over a significant time period and also the rainfall intensity needs to approximate the saturated coefficient of permeability of the soil at the ground surface.

Hydraulic characteristics such as saturated coefficient of permeability and initial degree of saturation, intensity and duration of rainfall are parameters which are important in the analysis of slope stability considering rain infiltration.

According to Biot's theory of consolidation, to analyze the behaviour of unsaturated soils, is required to simultaneously compute deformation and groundwater flow with time dependent boundary conditions (fully coupled flow deformation analysis).

Hydraulic Models

Van Genuchten (1980) presented a set of closed-form equations of hydraulic characteristics for unsaturated soils which is based on the capillary model of Mualem (1976). The Van Genuchten model introduced the relation between saturation and suction pore pressure head (ϕ_p):

$$S_{\phi_p} = S_{\text{residu}} + \frac{S_{\text{sat}} - S_{\text{residu}}}{1 + g_a \phi_p^{g_n g_c}}$$

$$\phi_p = - \frac{u_w}{\rho_w g}$$

where S_{residu} is the residual degree saturation of the soil that describes the part of water that remains in the soil even at high suction heads. S_{sat} is the degree saturation of the soil when the pores are filled with water. g_a , g_n and g_c are empirical parameters, and it is assumed that:

$$g_c = \frac{1 - g_n}{g_n}$$

Hydraulic Models

The Van Genuchten Model is used in which the effective degree of saturation (S_e) is obtained as:

$$S_e = \frac{S - S_{\text{residu}}}{S_{\text{sat}} - S_{\text{residu}}}$$

The relative permeability in relation to Mualem – Van Genuchten is:

$$k_{\text{rel}} S = S_e^{g_l} \left(1 - \left(1 - S_e^{\frac{g_n}{g_l-1}} \right)^{\frac{g_n-1}{g_n}} \right)^2$$

where g_l is an empirical parameter.

Shear Strength of Unsaturated Soil

The principle of effective stress is applicable for saturated soils. For unsaturated soils, the water phase fills only parts of the pore volume, whereas the remainder is occupied by air. Bishop (1959) has modified Terzaghi's classical effective stress theory and presented the matric suction coefficient (χ) for the effective stress of unsaturated soils:

$$\sigma' = \sigma - u_a + \chi u_a - u_w$$

where σ' and σ are the effective and total stress respectively, u_a is the pore air pressure, and u_w is pore water pressure. The term $(u_a - u_w)$ is called matric suction and χ is the matric suction coefficient and varies from 0 to 1 covering the range from dry to fully saturated conditions.

By assuming that the pore air pressure is constant and is small enough to be neglected ($u_a \approx 0$), consequently for a dry soil, effective stress and total stress are the same. The matric suction coefficient (χ) is usually obtained from laboratory tests on both saturated and unsaturated samples.

Oberg and Salfors (1997) and Vanapalli et al. (1996) suggested that the factor χ can approximately be replaced by the degree of saturation or the effective degree of saturation, because the shear strength of unsaturated soils is strongly related to the amount of water in voids of soils and in turn to the matric suction.

Consequently, the effective stress equation can be simplified to:

$$\sigma' = \sigma - S u_w$$

where S is the degree saturation of the soil.

Figure : Determination of matric suction coefficient.

Matric Suction Profile

The matric suction profile will come to equilibrium at a hydrostatic condition when there is a zero net flux from the ground surface. If moisture is extracted from the ground surface such as evaporation, the matric suction profile will be drawn to the left. If moisture enters at the groundwater surface such as infiltration, the matric suction profile will be drawn to the right.

Figure : Matric suction profile in horizontally layered unsaturated soil profiles

Example of Unsaturated Soil Slope

In this part slope stability analysis of unsaturated soils due to rain infiltration will be discussed. A simple case of a homogeneous slope has been chosen. The international soil classification system USDA series is used for determining the hydraulic data for the analysis. The mechanical and hydraulic models used in the analysis are the Mohr Coulomb failure criterion and the Van Genuchten model respectively. The height of the slope is 10 m and the gradient (horizontal to vertical) is 2:1.

Figure : Geometry and two dimensional finite element mesh (4800 15-noded elements)

Soil Parameters

Soil parameters for the Mohr Coulomb model used in the analysis:

Description	Symbol	Unit	Value
Unit weight	γ	kN/m ³	20
Elasticity modulus	E'	kPa	7500
Effective poisson's ratio	ν'	-	0.35
Effective cohesion	c'	kPa	20
Effective friction angle	ϕ'	°	20

Hydraulic Parameters

Four different hydraulic parameter sets of the USDA series for the Van Genuchten Models are used to evaluate the effect of these parameters in slope stability during rain infiltration:

Texture	K_{sat} (m/s)	g_a (1/m)	g_n (-)	g_l (-)
Sand	8.25E-05	14.50	2.68	0.50

Boundary Conditions

The initial ground water level was assumed to be horizontal at level of the toe of the slope. A rainfall with intensity of 10 mm/hour lasting 3 days (72 hours) was applied on the crest and the slope. The minimum and the maximum pore pressure head respectively are -0.1 m ($\theta_{\min}$) and 0.1 m ($\theta_{\max}$). The left boundary, right boundary and lower boundary of the model were assumed impervious boundaries.

Figure : Boundary conditions of the model.

Initial Degree of Saturation

Initial degree of saturation for the four different hydraulic parameters leading to different initial degree of saturation at the same suction:

Figure : Initial conditions: degree of saturation.

Initial Suction

Initial suction in the model is assumed to increase linearly above ground water level until ground surface.

72	1.690	1.611	1.436	1.229

Conclusions

- Safety factors from FEM compare well with factors obtained from LEM.
- FEM for slope stability is more powerful than LEM. The failure mechanisms in FEM are computed automatically as part of the stress equilibrium process.
- Effect of rainfall infiltration, leading to change of suction and saturation in slope, on factor of safety can be assessed.
- During the time of rain infiltration, suction decreases and thus the FOS of the slope reduces, whereas the reduction is faster for soils with high permeability than for soils with low permeability.

EXERCISE 1: Slope stability analysis
(fully saturated slopes)

Indra Noer Hamdhan

COMPUTATIONAL GEOTECHNICS

INTRODUCTION

The exercise concerns the stability of a slope in short term condition. In order to keep the problem as simple as possible, only the Mohr Coulomb material model is considered. Besides the procedure to generate the finite element mesh, attention is paid to the input of boundary conditions, material properties, the actual calculation and inspection of some output results.

AIMS

- Geometry input
- Parameters
- Calculation of FOS of the slope

Figure 1: Scheme of the exercise (Griffiths and Lane, 1999)

SCHEME OF OPERATIONS:

GEOMETRY INPUT

- Project properties
- Defining of soil stratigraphy
- Material data sets
- Defining of slope geometry
- Mesh generation

PERFORMING CALCULATIONS

- Initial conditions
- Phase 1 (safety analysis)
- Execution of calculation
- Viewing calculation results

THE SAFETY FACTOR

- The safety factor

GEOMETRY INPUT

2D Start PLAXIS by double-clicking the icon of the Input program.

- A 'Quick Select' dialog box will appear in which you can select an existing project or create a new one.
- Choose 'Start a new project' (see Figure 2). Now the 'Project properties' window appears, consisting of the two tabsheets 'Project' and 'Dimensions' (see Figure 3 and Figure 4).

Figure 2: Quick Select dialog box

Project Properties

The first step in an analysis is to define the basic parameters of the finite element model. This is done in the 'Project properties' window. These settings include the description of the problem, the type of analysis, the basic type of elements, the basic units and the size of the drawing area.

In order to enter the proper settings for the footing project, follow these steps:

- In the 'Project' tabsheet, enter "Slope Exercise 1" in the 'Title' box and type "Slope stability analysis without considering suction" or any other text in the 'Comments' box.

- In the 'Model' tabsheet, keep the default units in the Units box (Unit of Length = m; Unit of Force = kN; Unit of Time = day).
- In the 'Model' tabsheet, the type of the analysis (*Model*) and the basic element type (*Elements*) are specified. As this exercise concerns a slope stability, choose 'Plane strain' from the 'Model' combo box. Select '15-Node' from the 'Elements' combo box.
- The 'General' group the gravity is 1.0g (-Y direction, which is in the vertical direction) and earth gravity is 9.810 m/s^2 and the unit weight of water γ_{water} is set to 10 kN/m^3 .

Figure 3: Project tabsheet of the Project properties window

- In the 'Contour' group the size of the considered geometry must be entered. The values entered here determine the size of the drawing area in the Input window. PLAXIS 2D will automatically add a small margin so that the geometry will fit well within the draw area. Enter the following values in the boxes ' x_{min} ', ' x_{max} ', ' y_{min} ', ' y_{max} ' – 0.0; 60.0; 0.0; 15.0.
- Click on the button to confirm the settings. Now the drawing area appears in which the geometry model can be drawn.

Hint: For changing the general settings, one can access the 'Project properties' window by selecting the 'Project properties' option from the 'File' menu.

Figure 4: Model tabsheet of the Project properties window

Defining of soil stratigraphy

Information on the soil layers is entered in boreholes. Boreholes are locations in the draw area at which the information on the position of soil layers and the water table is given. If multiple boreholes are defined, PLAXIS 2D will automatically interpolate between the boreholes. The layer distribution beyond the boreholes is kept horizontal. In order to construct the soil stratigraphy follow these steps:

- Click the *Create borehole* button in the side (vertical) toolbar to start defining the soil stratigraphy.
- Click at $x = 0$ in the draw area to locate the borehole. The *Modify soil layers* window will appear.
- In the *Modify soil layer window* add a soil layer by clicking the *Add* button.
- Set the top boundary of the soil layer at $y = 5$ and keep the bottom boundary at $y = 0$ m.
- By default the *Head* value (groundwater head) in the borehole column is set to 0 m. Set the Head to 5.0m (Figure 5).

Figure 5: Modify soil layer window.

The creation of material data sets and their assignment to soil layer is described in the following section.

Material data sets

In order to simulate the behaviour of the soil, a suitable soil model and appropriate material parameters must be assigned to the geometry. In PLAXIS 2D, soil properties are collected in material data sets and the various data sets are stored in a material database. From the database, a data set can be assigned to one or more soil layers. For structures (like walls, plates, anchors, geogrids, etc.) the system is similar, but different types of structures have different parameters and therefore different types of material data sets. PLAXIS 2D distinguishes between material data sets for 'Soil and Interfaces', 'Plates', 'Anchors', 'Embedded pile row' and 'Geogrids'.

The creation of material data sets is generally done after the input of boundary conditions. Before the mesh is generated, all material data sets should be defined and all clusters and structures must have their appropriate data set.

To create of material set for soil layer, follow these steps:

Open the *Material sets* window by clicking the *Materials* button in the *Modify soil layers* window. The material sets windows pops up (Figure 6).

Figure 6: Material sets window.

- Click the *New* button at the lower side of the Material sets window. A new window will appear with five tabsheets: General, Parameters, Flow Parameters, Interface and Initial.
- Enter the proper values in the 'General properties' box according to the material properties listed in **Error! Reference source not found.** (see also **Error! Reference source not found.** and **Error! Reference source not found.**).
- Hydraulic model, data set, soil type, values of permeability, and initial void ratio can be entered in the 'Parameter' box of the 'Flow parameters' tabsheet. (see **Error! Reference source not found.**)
- Since the geometry model does not include interfaces, the fourth tabsheet 'Interfaces' can be skipped.
- Click OK to confirm the input of the current material data set. Now the created data set will appear in the tree view of the 'Material Sets' window.

Figure 7: General tabsheet of the soil and interface data set window.

Figure 8: Parameters tabsheet of the soil and interface data set window.

Figure 9: Flow parameters tabsheet of the soil and interface data set window.

The material properties of the soil layer are listed in the following table.

Parameter	Symbol	Soil	Unit
General			
Material model	Model	Mohr Coulomb	-
Type of material behaviour	Type	Undrained A	-
Soil unit weight above phreatic level	γ_{unsat}	18,0	kN/m ³
Soil unit weight below phreatic level	γ_{sat}	20,0	kN/m ³
Parameters			
Young's modulus	E_{ref}	10000	kN/m ²
Poisson's ratio	ν	0,30	-
Cohesion	c'	10,0	kN/m ²
Friction Angle	ϕ'	20,0	°
Flow parameters			
Data set	-	USDA	-
Model	-	Van Genuchten	-
Soil type	-	Silt	-
Permeability x-dir.	k_x	0,5996	m/day
Permeability y-dir.	k_y	0,5996	m/day

Table 1: Material properties

Van Genuchten model is the model that describes the hydraulic behaviour of unsaturated soil. In this model Soil Water Characteristic Curve (SWCC) is introduced to describe hydraulic parameters of the groundwater flow in unsaturated zones (usually above the phreatic surface). This input information is not used in Exercise 1, but will be used in the following exercises.

- Drag the set *Soil* from the *Material sets* window (select it and hold down the left mouse button while moving) to the graph of the soil column on the left hand side of the Modify soil layers window and drop it there (*release the left mouse button*).
- Click *OK* in the *Material sets* window to close the database.
- Click *OK* to close the *Modify soil layers* window.

Defining of slope geometry

The slope is defined in the *Structures* mode. To define slope layers:

Click the *Create soil polygon* button in the side toolbar and select the Create soil polygon option in the appearing Menu.

- Define the slope in the draw area by clicking on (0.0 5.0), (0.0 15.0), (20.0 15.0) and (40.0 5.0).
- Right-click the created polygon and assign the slope data set to the soil polygon (Figure 10).
- Final model geometry will be appear (Figure 11)

Figure 10: Assignment of a material dataset to a soil cluster in the draw area.

The proposed geometry does not include plates, hinges, geogrids, interfaces, anchors or tunnels. Hence, you can skip the corresponding buttons in the toolbar.

Figure 11: Final geometry of the model.

Mesh Generation

In order to generate the mesh, follow these steps:

- Proceed to the *Mesh* mode by clicking the corresponding tab.

Click the *Generate mesh* button in the side toolbar. The *Mesh options* window pops up.

- Select the *Very Fine* option as element distribution.
- Click OK to start the mesh generation.

Figure 12: Mesh options window.

As the mesh is generated, click the *View mesh* button. A new window is opened displaying the generated mesh (Figure 13).

Figure 13: The generated mesh in the *Output* window.

Click on the 'Close' tab to close the *Output* program and back to the *Mesh* mode.

PERFORMING CALCULATIONS

Once the mesh has been generated, the finite element model is complete.

Initial Conditions

Click the *water conditions* tab to show the initial water conditions that already defined (Figure 14).

Figure 14: The initial water conditions.

The 'Initial phase' always involves the generation of initial conditions. In general, the initial conditions comprise the initial geometry configuration and the initial stress state, i.e. effective stresses, pore pressures and state parameters, if applicable.

Click the *Staged construction* tab to proceed with the definition of calculation phases. When a new project has been defined, a first calculation phase named "Initial phase", is automatically created and selected in the *Phases explorer* (Figure 15). All structural elements and loads that are present in the geometry are initially automatically switched off; only the soil volumes are initially active.

Figure 15: Phases explorer.

The *Phases* window (Figure 16) is displayed by clicking the *Edit phase* button or by double clicking on the phase in the *Phase explorer*.

Choose 'Gravity Loading' from the 'Calculation type' combo box of the 'General' tabsheet.

Figure 16: The Phases window for Initial phase.

The *Staged construction* option is available as Loading type.

The *Phreatic* option is selected by default as the *Pore pressure calculation type*.

Hint: As a rule, one should use The '*K₀-procedure*' only in cases with a horizontal surface and with all soil layers and phreatic levels parallel to the surface. For all other cases, *Gravity Loading* should be used.

- In the *Model explorer* expand the *Model conditions* subtree.
- Expand the *Deformations* subtree. Note that the *Use default fixities* box is checked. By default, a full fixity is generated at the base of the geometry, whereas roller supports are assigned to the vertical boundaries ($u_x = 0$; $u_y = \text{free}$).
- Expand the *Water* subtree. The water level generated according to the *Head value* assigned to boreholes in the *Modify soil layer* window (BoreholeWaterLevel_1) is automatically assigned to *GlobalWaterLevel* (Figure 17).

Figure 17: The *Deformations* and *Water* subtrees in the *Model explorer*.

Phase 1 (safety analysis):

In order to simulate slope stability analysis, a safety analysis is required. In order to define the calculation phase follow these steps:

Click the *Add phase* button in the *Phases explorer*. A new phase, named *Phase_1* will be added in the *Phases explorer*.

- Double-click *Phase_1* to open the *Phases* window.
- In the *ID* box of the *General* subtree, write (optionally) an appropriate name for the new phase (for example “safety analysis”).
- The current phase starts from the *Initial phase*, which contains the initial stress state. The calculation type is *Safety*, Loading type Incremental multiplier with Msf 0.1 (see **Error! Reference source not found.**).
- Check list *Ignore suction* in Deformation control parameters.

Figure 18: Parameters tabsheet of the first calculation phase

The information, which is continuously updated, shows the calculation progress, the current step number, the global error in the current iteration and the number of plastic points in the current calculation step. It will take a few seconds to perform the calculation. When a calculation ends, the window is closed and focus is returned to the main window.

The phase list in the *Phases explorer* is updated. A successfully calculated phase is indicated by a check mark inside a green circle.

Save the project before viewing results.

Viewing calculation results:

Press the 'View calculation' button that will start the output program.

Check the various types of output, such as the deformed mesh, displacement contours, effective (principal) stresses, incremental strain, etc. These can be found from the '*Deformations*' and '*Stresses*' menus. Figure 21 illustrates incremental deviatoric strain $\Delta\gamma$ at the end of safety phase that indicates the failure mechanism of the slope.

Figure 21: Incremental deviatoric strain $\Delta\gamma_s$ at the end of safety phase

THE SAFETY FACTOR

The safety factor can be obtained from edit phases button at the Phases explorer. The reach values of ΣMsf – Reached safety factor represent the safety factor, provided that this value is indeed more or less constant during the previous few steps.

The best way to evaluate the safety factor is to plot a curve in which the parameter ΣMsf is plotted against the displacement of a certain node. Although the displacements are not relevant, they indicate whether or not a failure mechanism has developed.

In order to evaluate the safety factor in this exercise, follow these steps:

Start the curves program by clicking on the '*Curves manager*' button in the output program.

- Create a new chart by clicking the  button and select the appropriate problem in the file requester.
- The 'Curve Generation' window as indicated below (see Figure 22) will appear.
- In the *Curve generation* window, select Point A for the x-axis. Select *Deformations* → *Total displacements* → $|u|$ (absolute)
- For the y-axis, select *Project* and then select *Multipliers* → ΣMsf . The safety phases are considered in the chart. As a result, the curve of Figure 23 appears.

The maximum displacements plotted are not relevant. If the mouse cursor moves over a point on the curve, a box showing the exact value can be obtained.

EXERCISE 2: **Slope stability analysis**
 (partially saturated slopes)

COMPUTATIONAL GEOTECHNICS

INTRODUCTION

When unsaturated soils are considered and the effect of negative pore water pressure or suction is taken into account. This condition uses Bishop's definition of stress instead of Terzaghi's stress and is suitable for calculating unsaturated response of soils and for performing fully coupled hydro-mechanical behaviour of soils.

Terzaghi's principle effective stress theory is given by: $\sigma' = \sigma - p_w$

Bishop's principle effective stress theory is given by: $\sigma' = (\sigma - p_a) + \chi(p_a - p_w)$

Where σ' is effective stress, σ is total stress, p_w is pore water pressure, the term $(p_a - p_w)$ is called matric suction and χ is the matric suction coefficient and varies from 0 to 1 covering the range from dry to fully saturated conditions. By assuming that the pore air pressure p_a is constant and is small enough to be neglected ($p_a \approx 0$) and matric suction coefficient (χ) is can approximately be replaced by the effective degree of saturation, consequently, the effective stress equation can be simplified to: $\sigma' = \sigma - S_e p_w$

where S_e is the effective degree of saturation. This modified principle effective stresses is used when the suction is taken into account.

AIMS:

- To understand the effect of negative pore water pressure or suction in a slope stability analysis.

SCHEME OF OPERATIONS:

Geometry input

- Use previous input file without change of:
 - o Project properties
 - o Defining of soil stratigraphy
 - o Material data sets
 - o Defining of slope geometry
 - o Mesh generation
- Save as new data file

PERFORMING CALCULATIONS

- Use previous initial conditions
- Phase 1 (safety analysis)
- Execution of calculation
- Viewing calculation results

THE SAFETY FACTOR

- The safety factor
- Inspect the safety factor and compare with slope stability analysis without considering suction.

GEOMETRY INPUT - USE PREVIOUS INPUT FILE

2D Start PLAXIS by clicking on the icon of the Input program.

- Select the existing project file from the last exercise (Slope Exercise 1).
- From the 'File' menu select 'Save As' and save the existing project under a new file name (e.g. 'Slope Exercise 2')

PERFORMING CALCULATIONS - Re-run existing calculation-list

- Uncheck list *Ignore suction* in option of Deformation control parameters in the *Phases explorer* (Figure 24).

Figure 24: Uncheck Ignore suction in the Phases explorer

3D Click the 'Calculate' button. This will start the calculation process (Figure 25).

Figure 25: Active task window displaying the calculation progress.

The information, which is continuously updated, shows the calculation progress, the current step number, the global error in the current iteration and the number of plastic points in the current calculation step. It will take

a few seconds to perform the calculation. When a calculation ends, the window is closed and focus is returned to the main window.

The phase list in the *Phases explorer* is updated. A successfully calculated phase is indicated by a check mark inside a green circle.

Save the project before viewing results.

Viewing calculation results:

Press the 'View calculation' button that will start the output program.

- **Error! Reference source not found.** illustrates incremental deviatoric strain $\Delta\gamma_s$ at the end of safety phase that indicates the failure mechanism of the slope. Figure 27 and Figure 28 show the suction profile of the slope. Figure 29 and Figure 30 show the profile of degree of saturation of the slope.

Figure 26: Incremental deviatoric strain $\Delta\gamma_s$ at the end of safety phase

Figure 27: Suction

Figure 28: Cross section of suction

Figure 29: Degree of saturation

Figure 30: Cross section of degree of saturation

THE SAFETY FACTOR

In order to evaluate the safety factor in this exercise, use the same procedure as used in the previous exercise. Figure 31 shows the ΣMsf against the displacement curve.

To compare the results obtained with both calculation modes plot both $\Sigma Msf -|u|$ curves in one chart.

In order to make a comparison of result in the curve generated, follow these steps:

- From the *Format* menu select *Settings* and Figure 32 will appear.
- Select *Add curve* and select *From another project (all)* and then select and open previous project file *Slope Stability Exercise 1*. Use the same steps to generate the curve and Figure 33 will appear. Use the manual scaling in the *Chart* tab to change the scale of the chart.

Figure 31: Evaluation of safety factor

Figure 32: Format setting window

Figure 33: Safety factors with two different Calculation modes

**EXERCISE 3: Slope stability analysis subjected to Rainfall
Infiltration (*partially saturated slopes*)**

COMPUTATIONAL GEOTECHNICS

INTRODUCTION

Slope stability analysis of unsaturated soil subjected to rainfall infiltration requires to compute simultaneously the deformations and groundwater flow with time dependent boundary conditions (fully coupled flow-deformation analysis). The calculation will be performed that considering the suction uses Bishop's definition of stress instead of Terzaghi's stress and Biot's theory of consolidation.

AIMS:

- To understand the change of negative pore-water pressure or suction during rainfall infiltration. This change of suction will influence the stability of the slope.

Figure 34: Scheme of the exercise (Griffiths and Lane, 1999)

SCHEME OF OPERATIONS:

Geometry input

- Use previous input file with change of:
 - Project properties
 - To reduce the computational time, 6-noded elements are used in this exercise. But nevertheless, 15-noded elements would give more accurate results for safety analysis.
 - Mesh generation
- Save as new data file

PERFORMING CALCULATIONS

- Use previous initial conditions
- Phase *fully coupled flow-deformation*.
- Phase *safety analysis*.
- Execution of calculation
- Viewing calculation results

THE SAFETY FACTOR

- Inspect the safety factor during rainfall infiltration.

GEOMETRY INPUT - USE PREVIOUS INPUT FILE

Start PLAXIS by clicking on the icon of the Input program.

- Select the existing project file from the last exercise (Slope Exercise 2).
- From the 'File' menu select 'Save As' and save the existing project under a new file name (e.g. 'Slope Exercise 3')

GEOMETRY INPUT

Project properties

- Change the elements by selecting the item 'Project properties' from the 'File' menu. Select the "6-Node" for Elements in Model tabsheet. (see Figure 35).

Figure 35: Elements: 6-Noded

Mesh generation

Use the procedure described before to generate the mesh after the change to 6-noded elements.

PERFORMING CALCULATIONS

- Delete old calculation phases.

Calculation Phases

This analysis consists of six phases. From the first phase until third phase a *Fully coupled flow-deformation analysis* is performed. During rainfall infiltration deformations and groundwater flow are computed

simultaneously with time dependent boundary conditions (fully coupled flow-deformation analysis). From the fourth phase until seventh phase, safety analyses are performed.

In order to perform all the calculation phases, follow these steps:

Phase 1 (1st day of Rainfall):

Click the *Add phase* button in the *Phases explorer*. A new phase, named *Phase_1* will be added in the *Phases explorer*.

- Double-click *Phase_1* to open the *Phases* window.
- In the *ID* box of the *General* subtree, write (optionally) an appropriate name for the new phase (for example “1st day of rainfall”).
- The current phase starts from the *Initial phase*, which contains the initial stress state. The calculation type is *fully coupled flow-deformation* and time interval is 1 day (see **Error! Reference source not found.**).

Figure 36: Phases explorer – Calculation type: fully coupled flow-deformation.

- Uncheck list *Ignore suction* in Deformation control parameters.
- In the *Model explorer* expand the *Model conditions* subtree.
- Expand the *Precipitation* subtree. Fill the parameters q (infiltration) = 0.2 m/day, $\psi_{\max} = 0.1$ m, and $\psi_{\min} = -1.0$ m (see **Error! Reference source not found.**).

Figure 37: Model explorer – Model condition – Precipitation subtree

Phase 2 (2nd day of Rainfall):

Click the *Add phase* button in the *Phases explorer*. A new phase, named *Phase_2* will be added in the *Phases explorer*.

- Double-click *Phase_2* to open the *Phases* window.
- In the *ID* box of the *General* subtree, write (optionally) an appropriate name for the new phase (for example “2nd day of rainfall”).
- Use the same procedure as used in the Phase 1 for the input of the *General* in *Phases explorer* but without select *Reset displacement to zero*.

Phase 3 (3rd day of Rainfall):

Click the *Add phase* button in the *Phases explorer*. A new phase, named *Phase_3* will be added in the *Phases explorer*.

- Double-click *Phase_3* to open the *Phases* window.
- In the *ID* box of the *General* subtree, write (optionally) an appropriate name for the new phase (for example “3rd day of rainfall”).
- Use the same procedure as used in the Phase 2 for the input of the *General* in *Phases explorer*.

The calculation-list after Phase 3 from Slope Exercise 3 appears, as indicated below (see Figure 38).

Figure 38: The calculation-list after third calculation phase

Phase 4 to 7 (safety analysis):

- In Phase 4 to 7, stability calculations are defined for the phases 0 to 3 respectively. Initial factor of safety (FOS), FOS after 1st day of rainfall, FOS after 2nd day of rainfall and FOS after 3rd day of rainfall will be calculated in Phase 4 to 7 respectively.

Click the *Add phase* button in the *Phases explorer*. A new phase, named *Phase_4* will be added in the *Phases explorer*.

- Double-click *Phase_4* to open the *Phases* window.
- In the *ID* box of the *General* subtree, write (optionally) an appropriate name for the new phase (for example “Initial factor of safety (FOS)”.
- The current phase starts from the *Initial phase*, which contains the initial stress state. The calculation type is *Safety*, Loading type Incremental multiplier with Msf 0.1.
- The procedure repeat for Phase 5, Phase 6 and Phase 7 for FOS after 1st day of rainfall, FOS after 2nd day of rainfall and FOS after 3rd day of rainfall respectively.

he full calculation-list from Slope Exercise 3 appears, as indicated below (see Figure 39).

Figure 39: Calculation phase

Viewing calculation results:

Press the ‘*View calculation*’ button that will start the output program.

- Check the various types of output showing the suction, the degree of saturation and the failure mechanism, as presented in Figure 40 to Figure 51.

Figure 40: Initial suction

Figure 41: Suction after 1st day of rainfallFigure 42: Suction after 2nd day of rainfallFigure 43: Suction after 3rd day of rainfall

Figure 47: Degree of saturation after 3rd day of rainfall

Figure 48: Failure mechanism before rainfall

Figure 49: Failure mechanism after 1st day of rainfall

Figure 50: Failure mechanism after 2nd day of rainfall

Figure 51: Failure mechanism after 3rd day of rainfall

THE SAFETY FACTOR

In order to evaluate the safety factor in this exercise, use the same steps as described before. Figure 52 show the ΣMs_f against the displacement curve. The curve shows that the safety factor reduces during rainfall infiltration.

Figure 52: Evaluation of safety factor
